In the US, 144.390 is the standard frequency for APRS. In Europe it's 144.800. I see Byonics only sells a 144.800 model of their MicroTrak 300. Is there a reason we can't fly on 144.800? I know it's not I-gated, but is there any other reason? I've been looking for a band plan, but so far, I haven't found one for APRS online (I'll keep looking through).

Thanks, Zack,

I'll check it out. I do have plenty of electronic CAD experience with Tango Schematic and PCB - both of which are so user-friendly that I can pick it up and be going full speed in a few minutes even after being away from it for years. Unfortunately (or fortunately, depending) mine are DOS apps which no capiche IJPs, but I've found an app, CADConverter, that does a fair job of converting HPGL files to PDF, which I used for the payload schematics posted on eoss.org.

Hi Greg

That remains to be seen. As Mark mentioned in the original post, the spec
claims that you can exceed either the speed or altitude limit but not both,
just like the Garmin units that many people fly. Only a test flight will
tell us for certain. I'll be posting my flight results to the group.

I make my load line, the string between the balloon and parachute, about 20 feet long. I want to ensure the balloon fragments have every opportunity to fall over the side of the parachute.

The shroud lines on my near spacecraft are roughly the about circumference of the parachute. I do this based on something I read many years ago (I don't recall the reference now).

to us it all depends on what we are flying.

The Balloon tho chute distance is like others have said, at lease long enough that all the balloon remenains can fall completely way past the chute and shroud lines.

In our flights this is raarely a problem.

On a RF flight like a corssband repeater the chute is usually close to the payload. the gather where all the shroud lines come together, is usually 5 feet ot so from the payload, whatever is a convient left over piece of line. And then the line from the top of chute to balloon is usually long enough that the balloon leftovers can fall below the payload if possible..

Now a Video flight, the distance from payload to chute is similar,, but the distance between the chute and the balloon always depends on the wind at launch time if it's windy it will be about 100 feet long, and if it's calm then we go as much as 300 feet.

Hi Ron

SABRE is using a very long parachute to payload line, 50 to 75 feet. The only reason is to reduce the amount of swing and sway in the payload so we get video that's watchable without pails of Gravol. For balloon to patachute, it's 10-20 feet ... for no particular reason.

I'm coordinating a near space launch with Pete Sias for September 26th. The launch will take place in Salina and I'd like to invite everyone to the flight. This mission will carry five BaloonSats with Vernier LabPro dataloggers. The students making these BalloonSats are science majors at KU tht are taking classes to be science teachers. I plan to send a test tracker on this flight. The tracker is a design for the Popular Mechanics online article I'm writing.

I plan to make an October launch from Washburn University in October for their meteorology class. I'd like to invite near space crews to this one also.
On both flights I'll launch a tracker transmitting at 144.390. The callsign will be KD4STH-xx. I'll let everyone know the SSID once I pick the tracking module I'll fly.

Thanks

EOSS has standardized on 12 - 15 ft of lift line between the balloon and the 'chute apex. This allow the balloon to be laid out over the line prior to fill and still clear the parachute, and it also discourages latex shards from the bursting (exploding!) balloon from snagging in the 'chute and shroud lines.

I've started tying a loop of the load line around the twisted balloon neck
and then folding the neck over and taping the heck out of it.

Remember, you have three pounds of positive lift, so you must use les than
three pounds of tape.

What we do is twist the balloon neck while it's still attached to the filler by rotating the entire balloon two or three times. Then we tie the string around the twisted part of the neck and secure the other end by spring clip to something like a belt loop. Then we detach the filler, bend the neck in half over the knot into a U shape, and zip tie around that. Since the other end of the line is secured, if you happen to fumble during this operation you should be able to pull the balloon back down.

We also put a brass ring (about 3" dia.) in the bottom of the U before zip-tying. This makes a much easier handhold for the balloon than hanging onto just the neck.

what we have been doing for all twenty years so far is the following,

Once the balloon is filled to the correct amount of lift, while it's still attached to the filling apparatus, we tie a simple line around the neck as tight as possible about 5/8th os the way from the balloon transition to neck area to the end of the neck as seen here (filler assembly not in this picture, this was taken just now at the desk with a balloon remnant,

Then in this same location we tie the main balloon to chute support line as seen here,

Then we fold over the neck so that the support line is at the bottom of the "U" shaped area formed by the folding over, and then the neck is tied again in the mid section of the fold. as seen here,

This is a crappy tie up, I did it by myself at the desk so it's not very well done, with an extra set of hands it's much neater and tighter, but you get the idea.

and with this we never have had a failure yet. 47 flights,

Hi Ron,

For 1200's and 1500's and smaller, I use a clove hitch with a half hitch after just above the fill tube once fill is complete. Then the tube is pulled and the neck folded over and tied off with another clove hitch/half hitch and secured with duct tape. We've also used zip ties over the hitches, but they're overkill, it seems.

Norm Kjome just used the first set of hitches w/o folding the neck with good results.

The neck on Totex 2000's and 3000's are too thick to fold over, so we use a PVC neck adaptor using a modified PVC 1.5" M to 1/2" NPT F reducer (Spears P/N D2466 or 438-209) with an annular groove 0.6" W x 0.05" D and two holes in the flange to accept 4 ft of 500# nylon line. The adaptor is inserted into the neck and secured using a 2" nominal hose clamp. After fill, the 1/2" NPT fill pipe is replaced with a PVC plug, and the lift line is tied off to the two nylon loops running thru the holes in the adaptor flange. All 3 pieces of that hardware go bye-bye with the balloon, but total cost is only about $2.00 - small change compared to the price of the balloon and the He to fill it.

Aeronauts,

I've started to re-write the members link page, please look for it at; http://www.arhab.org/links.html . What I'd like you to do is take a look, send me any corrections, additions, or if you know I should... removals.

I know this is not complete, but this is all of the icons I currently have. If you group does not have an icon, let me know what I can put in that space. For example, can I use the letters of your name i.e. BNSP? Please send me too much information instead of not enough. I at least want an icon, eMail address for a contact, web site, etc. I plan to link eventually to the records page and pick up individual records to put on this page too. But that is a later effort.

I won't turn down any advise or ideas you have either. This is the 4th of the web sites that Ralph had originally published. It's amazing how much work that man was doing for all of us... WOW!

Right now I'm thinking of either the weekend of July 17 or July 24. Does anyone feel strongly either way?

Unless I can come up with something novel, I'm leaning towards keeping Thursday pretty simple - maybe a trip to the space museum in the evening for those who are in town.

Hi Zach,

We appreciate you working the dates early. EOSS has a flight scheduled for 17 July with the Univ of Colorado. The 24th would be fine or the first weekend in Aug.

I would prefer the 24th, or even the 31st. Mid to late July is pretty busy for our family.

Speaking of which, GPSL 2011 will probably be 7-10 July unless there's a preference for 30 June-3 July (the 4th is Monday in 2011). For me to do the necessary prep work in mid July to support a late July GPSL weekend would be nearly impossible. I'm tentatively planning a tour of the Strategic Air and Space Museum (formerly the SAC Museum) for the Thursday afternoon activity.

6023. CHDK

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-11 17:00:34 UTC
From: L. Paul Verhage
Topic: 6023 Message: 6023

This is way too cool. I've started playing with a Canon A550 after hearing Mark and Mike's comments. So far I've created a simple intervalometer that replaces the relay driven cameras I've used in the past. Since the A550 is not an S series camera, I don't have access to the flash. So I've manaully shut that off. Next I'd like to write the code for a camera pointed downward. It would take pictures more frequently at low altitude and less frequently at high altitude.

I wonder about using the lightning detection code to detect balloon burst, or if the expansion and movement of the balloon would be too much and trigger false positives.

CHDK is the shizzle. There are so many scripts out there doing so many things it's amazing.

The lightning detection script is a fast motion detector. The camera compares user selectable grids (select the number of squares in the view screen) for changes. It's 'sensitivity' is also selectable. While there would be a learning curve I am sure the script would do what you'd like.

I recently went to the Pyrotechnics Guild International's convention in Mason City, Iowa and used a motion detection script to photograph the fireworks. It worked very well in triggering the camera when the fireworks lit. http://s33.photobucket.com/albums/d94/bigheadpete/PGI%202009/

I'm going to add a sidebar to a future article about CDHK. I'll need to know which indivduals brought up CDHK on the list so I can give them credit. I can start searching old posts, but if you recall bringing p CDHK, let me know.

Now, if I could just get the Canon cameras for less.

Thanks,
Paul

The Canon A550 was pretty cheap (about $150 compared to the other Canons)
and 7.1 MP. I found mine listed under Amazon.com

Check again. It seems they're constantly cracking new cameras and getting
them ported for CHDK. You can often find cameras that work by looking on
Amazon and eBay for leftovers and refurbs.

6029. Re: [GPSL] CHDK

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-11 20:29:39 UTC
From: Mark Conner
Topic: 6023 Message: 6029

I noticed today that recent CHDK builds include shutter control via the
USB port, so that is possible for those wishing for microcontroller control.

However, it's nice to have a camera that is not at all dependent on other
electronics to function. I put a 4 Gb card in mine and shoot at 15 second
intervals and still don't fill the card up after a 3-hour flight.

I did find that if you use a card larger than 4 Gb, you cannot have the
camera boot the card's firmware automatically on power-up. This is because
FAT32 is required to format an 8 Gb card and the auto-boot function only
works on FAT16 cards.

Also, about the fastest the camera can take pictures is 4-5 second
intervals. I think it'll burst at a faster rate but can't sustain it. I
was hoping to make a time-lapse movie of a hot-air balloon flight, but it
didn't come out all that good because of the long interval.

OK, so I'm hearing the weekend of July 23-25, 2010 for GPSL? Objections
before I get things set into motion?

Personally, August is looking pretty busy for me, and the holiday
week/weekends don't work well for my crew.

Zack,

July 23-25 is fine with BASE, We should be there.

Thanks for hosting,
Howard

OK, so I'm hearing the weekend of July 23-25, 2010 for GPSL? Objections before I get things set into motion?

Personally, August is looking pretty busy for me, and the holiday week/weekends don't work well for my crew.

Right now I'm thinking of either the weekend of July 17 or July 24. Does anyone feel strongly either way?

Unless I can come up with something novel, I'm leaning towards keeping Thursday pretty simple - maybe a trip to the space museum in the evening for those who are in town.

Never having been to a GPSL but wanting to go I like the idea of setting the dates this far in advance. My vacation time is picked in December for the following year and changing it is difficult if not impossible.

I've converted it to uppercase. Just out of curiosity, why? Especially since you don't use all uppercase?

Hi Everyone

Well, we flew the Venus GPS logger on SABRE-7 yesterday and the results were inconclusive. I built a small package with a 250 mAh LiPo battery that would power the tracker for about 3 hours. The problem is that we underfilled the balloon and with barely 400 fpm of initial lift, it took 3 hours to reach 60,000. That's when either the GPS shut down or the battery quit. Rats! My gut feeling is that it was the battery but I can't be sure. I'm attaching all of my data and will let each of you make up your own minds.

One thing I did find during testing is that the current draw listed on the Sparkfun web page is very misleading. This current listed is only for the GPS. With the data logger circuitry it runs at about 60 mA. That explains why I only get 3 hours from a 250 mAh LiPo. Still very respectable. I also found that it worked great with just a passive patch antenna. Even with the passive antenna it was tracking 8 or more satellites outside, 4-6 in the living room and often 3-5 in the basement. That will save you another 10 mA. The GPS also runs quite warm to the touch so it should generate enough heat to keep itself and its batteries nice and warm with a bit of insulation.

This on is going to fly on our next flight, possibly next month. I'll keep you posted.

So does it work above 60,000 feet. Inquirying minds wnat to know.

On Wed, Aug 12, 2009 at 11:16 PM, Bruce Coates <bruce.coates@...> wrote:

Hi Greg

I just got mine and and it definitely does log the altitude. I even checked with the manufacturer just to be certain. It's also pretty efficient ac compressing the data. I cranked up the logging on mine to once per second and it recorded over 11 an a half minutes of data in just 6 kilobytes of memory or about a 10:1 compression ratio. Once you use the Log Decompress feature in Skytraq you end up with a clear text file in the format shown below. it also generates a KML file. Very cool. I hope to get this little fella up on our next flight later this month.

Hi,

We've had some success with the Venus GPS. It's integrated into our 'BadgerCub' flight computer:

http://www.cuspaceflight.co.uk/wiki/doku.php?id=badgercub

It flew successfully onboard the Nova 14 flight (above 60,000 ft):

http://www.cuspaceflight.co.uk/wiki/doku.php?id=nova_14

Some remarks:

- Check the design guidelines document carefully (http://www.sparkfun.com/datasheets/GPS/Modules/DesignNoticeOnCommonMistakes.pdf) - we've had to add a couple of green wires as a result of not reading it thoroughly first time round.

- As far as we can see, the binary protocol seems to be documented for setup only - i.e. the format of the binary nav data isn't published.

- The NMEA strings are fine for position fixes but don't give very good velocity information

- We've had an as yet unresolved issue where the GPS would stay in reset when the PPS signal was connected to the uC even though the uC pin was set as an input - could just be a mistake on our part we haven't figured out yet, but something to check if you are getting odd behaviour.

- Got (anecdotally) really great performance when teamed up with the Sarantel Antenna (SL1204). Got a lock upside down in our dungeon of a work-space where we haven't seen other GPS's lock very easily.

If we can answer any other questions, we will - we're in active development of the firmware for Badger2 (http://www.cuspaceflight.co.uk/wiki/doku.php?id=badger2) so we have datasheets and code at the tips of our fingers.

6042. RE: [GPSL] GPSL 2010 Dates

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-14 15:07:37 UTC
From: Nick Hanks
Topic: 6020 Message: 6042

Hi Zach,

A bit more detail on the email below. EOSS has a flight scheduled on 31 July (and the 17th) with a Univ of Colorado Space Grant program.

Nick

From: Nick Hanks [mailto:ndhanks@...]
Sent: Thursday, September 10, 2009 19:51
To: 'GPSL@yahoogroups.com'
Subject: RE: [GPSL] GPSL 2010 Dates

Hi Zach,

We appreciate you working the dates early. EOSS has a flight scheduled for 17 July with the Univ of Colorado. The 24th would be fine or the first weekend in Aug.

Nick

EOSS GPSL Coordinator

From: GPSL@yahoogroups.com [mailto:GPSL@yahoogroups.com] On Behalf Of Zack Clobes
Sent: Thursday, September 10, 2009 19:42
To: Group GPSL
Subject: [GPSL] GPSL 2010 Dates

Right now I'm thinking of either the weekend of July 17 or July 24. Does anyone feel strongly either way?

Unless I can come up with something novel, I'm leaning towards keeping Thursday pretty simple - maybe a trip to the space museum in the evening for those who are in town.

6043. OT, Smart Beaconing and Second Profile

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-15 20:56:22 UTC
From: Pete Lilja
Topic: 6043 Message: 6043

I've finally gotten an Open Tracker + to fly in a HAB with a (n old) Kenwood THG71A and a new Garmin 18 (just confirmed by Garmin Tech Support to work above 65,000'). The OT + seems to work very well and thanks to all of you GPSLers that suggested it to me several months ago.

The OT+ offers some possibilities I'd like to ask your opinions.

Smart Beaconing: What are some good parameters to use for HABing? What do you use?

Profile 1/2: Being able to change transmission parameters based on so many inputs through Profile 1/2 also makes me wonder what other have done with this OT+ capability. What have you done with this in HABing?

Thanks,

Pete

To my knowledge, no one uses smart beaconing for ARHAB. Most prefer regular intervals for transmissions. This is so that they can watch a clock and know when a transmission should be expected - if they don't hear one at the scheduled time, there's a problem.

Smart beaconing is normally done to detect sharp changes in direction (corner pegging) and to provide updates based more on distance rather than time (beacon more often when moving fast, much less when slow or stopped). For balloons, I still want packets once a minute whether the ground speed is 5 kts or 105 kts.

?
http://space.1337arts.com/

Not bad for $150 total, and they got it back so they can do it again. All off the shelf, the only "hacking" was using a CHDK-controlled camera.

The fact that they recovered the payload is amazing. As mentioned on the flight pictures page of their website,
http://space.1337arts.com/flight, they lost phone contact at 2500 feet on the ascent and visual contact after about 30 minutes. The loss of signal lasted almost three hours! They make reference to not having any altitude reported via the logs above 19,853 feet, and no transmissions after landing since the external antenna was buried in the soft earth.

The calm winds helped them tremendously since their predictions were from the Wyoming Balloon Trajectory program that uses ascent rates of about 900 feet/minute, and they estimated their ascent at about 400 feet/minute.

Sometimes it is nice to be lucky.

The PR on this is tremendous. I've seen this story pop up on some
national-level news/political blogs too.

It'll be interesting to see if this translates into a lot more attempts with
off-the-shelf components and equal (or less!) preparation. Their "$150"
cost neglected the helium, which was provided by a professor, so anyone
wanting to try this without any donations will be looking at a ~$250 cost.
A quarter-kilobuck may be over the pain threshold for many.

6048. GPSL 2010 Date Set

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-17 00:28:20 UTC
From: Zack Clobes
Topic: 6048 Message: 6048

The popular vote goes to Fri-Sat, July 23rd and 24th, 2010 in Hutchinson, KS. I'm working on some sort of optional activity for Thursday evening. Sunday will be reserved as a rain-date.

I will be working to get the website updated as soon as I have a few more details nailed down. In the meantime, I'd like to encourage you all to join the GPSL Twitter feed. I will be using Twitter throughout the event to disseminate news, updates, and to coordinate events. I promise not to inundate you with meaningless Tweets!

Oh, crap, so now I'm going to have to become a Twit to stay up on GPSL?

Seriously, though, I've thought about this for our NSTAR launches. Unfortunately, some other twit has taken twitter.com/nstar, used it twice last summer, quit. Argh. I know EOSS is using Twitter - has EOSS or any other group found Twitter to be useful for this?

Mark,

BASE_DePauw is our twitter account. It only works when I remember to tweet :) Ideally, we'd tweet the prelaunch announcement, the launch, time to reach 18 kft, 60 kft, burst, landing, and recovery.

As of this morning, I am now following two accounts: EOSS and Superlaunch.

I'm using Twitter for two accounts. The first is my Street Astronomer persona (streetastro) where I send out daily notes about what is happening in the sky. If you're in Kansas, you might want to listen in.

The second is NearSys (nearsys) where I give updates to my activities.

I also link the Tweets to my NearSys blog (nearsys.blogspot.com). In the blog I go into more details. Then there's the NearSys channel on YouTube where I post videos of activities that I mention in my tweets. I really need more time to do everything right.
:)

Not counting gas money to recover it :=}.

It's notable that we ARHAB guys were doing the same gig with student
payloads and tracking beacons over 20 years ago.

Spirit of Knoxville has a twitter at http://twitter.com/spiritofknox.

We havent updated it since April, but when we used it for the TA attempts it was very handy, and the followers were kept up to date with the latest telemetry.

6055. NSTAR pre-launch photo

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-18 01:01:22 UTC
From: Mark Conner
Topic: 6055 Message: 6055
Attachments: 1 described; binary payloads are missing from this source WARC

This was a chance photo captured by our payload camera during our last launch. If I think of it, I start the payload camera on its timed sequence before we start filling and point it in the general area where we are filling. Sometimes we capture some neat stuff that way. This particular one is cropped to show details.

Anyhow, this photo illustrates some things I've tried to describe verbally, so maybe it'll make more sense this way:

1) Zip ties for neck closure (flourescent green this time). On a damp morning like this one (it was very foggy on the way to the launch site), they are much easier to deal with than duct tape, and more secure. We use two because redundancy is cheap in this instance.

2) Brass ring. This is put in the bottom of the U after we tie the load line to the balloon but before we zip tie it. The balloon holder (Wayne KE6DZD in this case) can hold the balloon with a couple of fingers through the ring, a much more secure grip than around the neck (especially if he has to hold onto the balloon for some time while I'm troubleshooting). Ours are about 3" in diameter - smaller is kinda cramped for a two-finger

3) Load line clipped to belt. This is done before the balloon is detached from the filler. If the balloon holder should fumble the balloon, hopefully it'll go no farther than the load line's length. The excess line is wrapped around a small foam block, which should provide some resistance as the string unwinds before the line goes taut (not to mention keeping 15 ft of string corraled in the meantime). Hopefully this will prevent snapping the line from sudden tension should the worst happen.

From: Caitlin Mantych
Topic: 6048 Message: 6056

Hi everyone,
I hope things have been going well since the conference! The U of M Ballooning Team is getting some new projects ready for flight, but we need to float our balloon at altitude, something we have not done before. How do we go about doing this, and what is the best floating method? Any advice would be much appreciated.
Also, I remember reading that the BLAST! video could be requested by groups from the GPSL conference- who do I need to contact to find out more about this? Professor Flaten is teaching a freshman seminar this semester and would like to show the movie to his students.
Thanks so much!

I'm using Twitter for two accounts. The first is my Street Astronomer persona (streetastro) where I send out daily notes about what is happening in the sky. If you're in Kansas, you might want to listen in.

The second is NearSys (nearsys) where I give updates to my activities.

I also link the Tweets to my NearSys blog (nearsys.blogspot. com). In the blog I go into more details. Then there's the NearSys channel on YouTube where I post videos of activities that I mention in my tweets. I really need more time to do everything right.

:)

Paul

Mark,

BASE_DePauw is our twitter account. It only works when I remember to tweet :) Ideally, we'd tweet the prelaunch announcement, the launch, time to reach 18 kft, 60 kft, burst, landing, and recovery.

As of this morning, I am now following two accounts: EOSS and Superlaunch.

Oh, crap, so now I'm going to have to become a Twit to stay up on GPSL?

Seriously, though, I've thought about this for our NSTAR launches. Unfortunately, some other twit has taken twitter.com/ nstar, used it twice last summer, quit. Argh. I know EOSS is using Twitter - has EOSS or any other group found Twitter to be useful for this?

Hi Cait,

It depends a lot on how long you need to float and at what altitude or ranges of altitudes. If it's less than an hour and you don't care much about the altitude, then a lightly filled or "leaky" latex is the low-priced spread. Otherwise, you're into a plastic, and those come either from Aerostar in Palestine TX, at a price, or from Mark Caviezel NG0X, at possibly a more reasonable price.

If your payload weighs in over a few hundred grams, then you're pretty much into a zero-pressure bag, where the envelope volume is selected to be just a bit larger than the volume of the fill gas necessary to support the envelope and payload at the desired float altitude. The ZP is named because the fill gas is vented to atmosphere via vents, or slits, in the envelope near the neck. When the fill gas expands enough to fill the envelope, the excess spills out thru the vents, thus reducing gross lift to equal the system weight. The problem with ZPs is that the fill gas volume shrinks when it cools overnight, and thus the system will descend. This can be overcome by controlled dumping of ballast, but hauling up ballast requires more fill gas and thus a larger envelope - and once all the ballast is dumped, you'll come back down the next night.

The neater although much more difficult floater is the super-pressure bag, where the envelope volume is selected as above, but it's sealed off so the gas can't vent once it expands to fill the fixed envelope volume. The hard part comes in making the envelope strong enough to prevent bursting once the gas pressure rises with solar heating. This isn't beyond normal polyethylene film strength for small volumes and light neck loads, but it gets real dicey for heavier stuff. The kewl part about the SP is that it will float at a density altitude, day and night, until it's cut down or it fails due to UV degradation.

Plastic balloons present a couple of complications compared to latex:

1) You MUST provide some means to terminate the flight when the mission is complete or gets into trouble. That typically involves cutting the payload string away AND opening a hole in the envelope to bring it down as well. This may require tow separate devices, one for the payload and one for the envelope. And neither should depend on a single-fault command system - the typical redundant terminator comprises a timer set to fire after the expected mission duration. Some cheap schemes which have worked include taping a few kg of weight to the top of a ZP, such that it tips over when the payload is cut away, thus letting the gas vent thru the neck vents. Another is destruct panel that gets pulled into the envelope by a long line tied to the payload, such that when the payload is cut away from the neck, the panel, which is lightly sealed, pulls in and opens

a big vent at the top of the envelope; this scheme relies on some minimum payload weight, and may not work if the parachute snubs the jerk on the destruct line (it's happened!). Now, a deflated plastic bag can serve as a fair to middlin' "retarder", as some refer to parachutes, so you may be able to leave the payload attached to the neck, provided you have a reliable, redundant means to dump the fill gas, such as opening a vent at the top of the balloon.

2) It's bad form to leave a gas bag floating about in the airspace, and even worse it let it get munched on my ruminant livestock, where it can clog up their GI systems. So you must arrange to get the deflated bag back ASAP after it lands, and that means that you have to provide it with its own tracking beacon, unless the payload remains attached to the neck after termination.

That's about all I can recall from the last time EOSS dared fly a floater, but others may more insights and broader experience to share.

Good luck, Cait!

Some of us in the UK managed to repeat the success of Bill Brown's latex floaters at night - a couple of months ago James Coxon got an overnight float at 28km with a 1.5kg balloon and a ~500g payload. Float altitude was solid as a rock +/- 100m according to the GPS for nearly 7 hours - almost like there was some kind of feedback mechanism. I wish I understood the physics a bit more!

Check Bill Brown's presentation here:

Hi Cait,

? I have done three different methods for floating a latex balloon. The best time for a longer duration float is to launch a couple of hours prior to sunset and then valve off the excess helium lift before reaching the burst altitude. I recommend about 70,000 feet since that puts you into uncontrolled airspace and in the minimum wind field?as well.

? A daytime floater can last up to 6 hours but runs the risk of latex degradation by the UV radiation....I've had over 20 hour floats when running the mission mostly during the night.

Here are the three methods that I've successfully used so far:

1) Constant pinhole leak.? I use a piece of plastic conduit pipe with a 1/16" hole in the endcap that fits in the balloon nozzle....the UK group has also tried this by punching a pinhole directly into the balloon nozzle....but the hole size could vary using the UK method as things stretch out a bit....but they have successfully achieved float this way as well. The only part is that it?is not fullproof as you are actually floating at the burst altitude....it's about 50/50 whether it floats or bursts...if you get the pinhole a bit too large, then it won't even reach burst altitude and will slowly come back down.? In my flight tests last year, a 1/16" hole flown overnight floated between 98,000 feet to 107,000 feet for almost 17 hours. However, when I tried two 1/16" holes it only went up to 28,000 feet and came back down.

2) No vent/No pinhole float:? Precisely measure lift such that at balloon sunset the loss of solar lift equals the positive lift that you put in at launch....requires you to make sure the balloon is ascending at such a rate that it doesn't reach burst before sunset. I've done several 20 plus hour flights this way....need to keep the positive ascent rate below 300 ft/min for maximum chance of success.

3) valve system.? Best reliability and controllability....but requires an active servo system to remove a ball from the end of the plastic pipe to vent helium. With a ballast system, you can steer up and down a few times with this method. I can send you photos of my vent valve that plugs in the balloon nozzle when I get back to my house.

Hope this helps....will be glad to send info and a valve to you for a future flight.

For longer flights, you'll have to go to a plastic zero pressure or super pressure flight...the super pressure flight is extremely tricky to get the exact amount of helium just right. I've been involved with many of these kind of flights and can help out if you decide to go this route.

- Bill Brown WB8ELK

Subject: [GPSL] University of MN could use your advice!

Hi everyone,?

I hope things have been going well since the conference! The U of M Ballooning Team is getting some new projects ready for flight, but we need to float our balloon at altitude, something we have not done before. How do we go about doing this, and what is the best floating method? Any advice would be much appreciated.?

Also, I remember reading that the BLAST! video could be requested by groups from the GPSL conference- who do I need to contact to find out more about this? Professor Flaten is teaching a freshman seminar this semester and would like to show the movie to his students.?

Thanks so much!

Thanks Mike! You've given us a lot to consider. We want to float the balloon for a few hours to collect cosmic dust. I hope everything is going well by you- I'll let you know how our flight goes!

Hi Cait,

It depends a lot on how long you need to float and at what altitude or

ranges of altitudes. If it's less than an hour and you don't care much

about the altitude, then a lightly filled or "leaky" latex is the low-

priced spread. Otherwise, you're into a plastic, and those come either

from Aerostar in Palestine TX, at a price, or from Mark Caviezel NG0X,

at possibly a more reasonable price.

If your payload weighs in over a few hundred grams, then you're pretty

much into a zero-pressure bag, where the envelope volume is selected to

be just a bit larger than the volume of the fill gas necessary to support

the envelope and payload at the desired float altitude. The ZP is named

because the fill gas is vented to atmosphere via vents, or slits, in the

envelope near the neck. When the fill gas expands enough to fill the

envelope, the excess spills out thru the vents, thus reducing gross lift

to equal the system weight. The problem with ZPs is that the fill gas

volume shrinks when it cools overnight, and thus the system will descend.

This can be overcome by controlled dumping of ballast, but hauling up

ballast requires more fill gas and thus a larger envelope - and once all

the ballast is dumped, you'll come back down the next night.

The neater although much more difficult floater is the super-pressure bag,

where the envelope volume is selected as above, but it's sealed off so the gas can't vent once it expands to fill the fixed envelope volume. The hard part comes in making the envelope strong enough to prevent bursting once the gas pressure rises with solar heating. This isn't beyond normal polyethylene film strength for small volumes and light neck loads, but it gets real dicey for heavier stuff. The kewl part about the SP is that it will float at a density altitude, day and night, until it's cut down or it fails due to UV degradation.

Plastic balloons present a couple of complications compared to latex:

1) You MUST provide some means to terminate the flight when the mission is complete or gets into trouble. That typically involves cutting the payload string away AND opening a hole in the envelope to bring it down as well. This may require tow separate devices, one for the payload and one for the envelope. And neither should depend on a single-fault command system - the typical redundant terminator comprises a timer set to fire after the expected mission duration. Some cheap schemes which have worked include taping a few kg of weight to the top of a ZP, such that it tips over when the payload is cut away, thus letting the gas vent thru the neck vents. Another is destruct panel that gets pulled into the envelope by a long line tied to the payload, such that when the payload is cut away from the neck, the panel, which is lightly sealed, pulls in and opens a big vent at the top of the envelope; this scheme relies on some minimum payload weight, and may not work if the parachute snubs the jerk on the destruct line (it's happened!). Now, a deflated plastic bag can serve as a fair to middlin' "retarder", as some refer to parachutes, so you may be able to leave the payload attached to the neck, provided you have a reliable, redundant means to dump the fill gas, such as opening a vent at the top of the balloon.

2) It's bad form to leave a gas bag floating about in the airspace, and

even worse it let it get munched on my ruminant livestock, where it can clog up their GI systems. So you must arrange to get the deflated bag back ASAP after it lands, and that means that you have to provide it with its own tracking beacon, unless the payload remains attached to the neck after termination.

That's about all I can recall from the last time EOSS dared fly a floater, but others may more insights and broader experience to share.

Good luck, Cait!

Some of us in the UK managed to repeat the success of Bill Brown's
latex floaters at night - a couple of months ago James Coxon got an
overnight float at 28km with a 1.5kg balloon and a ~500g payload.
Float altitude was solid as a rock +/- 100m according to the GPS for
nearly 7 hours - almost like there was some kind of feedback
mechanism. I wish I understood the physics a bit more!

Check Bill Brown's presentation here:

Hi Bill!
I think we'd like to use the valve method you described. Professor Flaten mentioned it a few weeks ago but wasn't exactly sure how to go about implementing it. I'd like to take you up on your offer for the valve and more info; the launch is scheduled for October 10th. Thank you so much for your help; the whole team really appreciates it. Have you had any new and exciting ballooning adventures since we last saw each other? Talk to you soon, Cait

Hi Cait,

  I have done three different methods for floating a latex balloon. The best time for a longer duration float is to launch a couple of hours prior to sunset and then valve off the excess helium lift before reaching the burst altitude. I recommend about 70,000 feet since that puts you into uncontrolled airspace and in the minimum wind field as well.

  A daytime floater can last up to 6 hours but runs the risk of latex degradation by the UV radiation... .I've had over 20 hour floats when running the mission mostly during the night.

Here are the three methods that I've successfully used so far:

1) Constant pinhole leak. I use a piece of plastic conduit pipe with a 1/16" hole in the endcap that fits in the balloon nozzle....the UK group has also tried this by punching a pinhole directly into the balloon nozzle....but the hole size could vary using the UK method as things stretch out a bit....but they have successfully achieved float this way as well. The only part is that it is not fullproof as you are actually floating at the burst altitude.... it's about 50/50 whether it floats or bursts...if you get the pinhole a bit too large, then it won't even reach burst altitude and will slowly come back down. In my flight tests last year, a 1/16" hole flown overnight floated between 98,000 feet to 107,000 feet for almost 17 hours. However, when I tried two 1/16" holes it only went up to 28,000 feet and came back down.

2) No vent/No pinhole float: Precisely measure lift such that at balloon sunset the loss of solar lift equals the positive lift that you put in at launch....requires you to make sure the balloon is ascending at such a rate that it doesn't reach burst before sunset. I've done several 20 plus hour flights this way....need to keep the positive ascent rate below 300 ft/min for maximum chance of success.

3) valve system. Best reliability and controllability. ...but requires an active servo system to remove a ball from the end of the plastic pipe to vent helium. With a ballast system, you can steer up and down a few times with this method. I can send you photos of my

vent valve that plugs in the balloon nozzle when I get back to my house.

Hope this helps....will be glad to send info and a valve to you for a future flight.

For longer flights, you'll have to go to a plastic zero pressure or super pressure flight...the super pressure flight is extremely tricky to get the exact amount of helium just right. I've been involved with many of these kind of flights and can help out if you decide to go this route.

- Bill Brown WB8ELK

Subject: [GPSL] University of MN could use your advice!

Hi everyone,

I hope things have been going well since the conference! The U of M Ballooning Team is getting some new projects ready for flight, but we need to float our balloon at altitude, something we have not done before. How do we go about doing this, and what is the best floating method? Any advice would be much appreciated.

Also, I remember reading that the BLAST! video could be requested by groups from the GPSL conference- who do I need to contact to find out more about this? Professor Flaten is teaching a freshman seminar this semester and would like to show the movie to his students.

Thanks so much!

Oh, crap, so now I'm going to have to become a Twit to stay up on GPSL?

Seriously, though, I've thought about this for our NSTAR launches. Unfortunately, some other twit has taken twitter.com/ nstar, used it twice last summer, quit. Argh. I know EOSS is using Twitter - has EOSS or any other group found Twitter to be useful for this?

OK Cait, glad to help out.

One option I failed to mention was a controlled dump valve on a latex. This will work to float the balloon well below burst, but does involve some complexity in that running wires up the lift line to the neck of the balloon is a recipe for failure; the line WILL twist - a LOT - even to the point of knotting, and that spells doom for any cable running in parallel with it. Twisting can be prevented by making the lift line in the form of a rope ladder, with two lines separated by spreaders spaced vertically roughly the horizontal distance between the lines and torsion couplers at the balloon neck and parachute apex. Or so I've reckoned - never tried it, but we've sure broken plenty of cords running even ten ft of payload or lift line! And be SURE to put plenty of slack in the copper to accommodate up to 50% stretch in the nylon at the tensile limit.

GL with the flight!

6064. floaters for MN?

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-21 13:02:14 UTC
From: K. Mark Caviezel
Topic: 6064 Message: 6064

Caitlin,
Mike laid out a pretty good primer* ** regarding floater balloons.
Indeed I have flown a bunch of zero pressure balloons, both from Aerostar and Global Western. I've also supplied zero pressure balloons to UTARC***, UKHAS, ANSR, TVNSP, Bill Brown, and clients in Germany, South Africa, Puerto Rico, Peru, and Canada. And we have a 'fast ascender' program ramping up for use by severe weather meteorologists at the NOAA National Severe Storms Laboratory.

Depending on your mission goals, a 'leaky latex' as Bill Brown has pioneered may be the most convenient and affordable. Otherwise, a clear plastic helium filled zero pressure floater may serve you well.

best regards,

- Mark Caviezel

* Mike did not mention air-filled solar balloons. These are technically zero pressure balloons, but they are 100% filled at launch with air. They heat up due to the sun's heating and fly away. They can give stable floats of over 10 hours and will descend at sunset. If you check youtube user 'kmcaviezel' you can see a launch video of my last solar balloon: 5+ pounds to 50,000 feet, about 14 hours aloft at the summer solstice.

** The requirement for two independent cut down devices applies to all non-exempt balloons, not only to plastic balloons. The FAA does not have a special set of rules only for plastic balloons.
Check
http://ecfr.gpoaccess.gov/cgi/t/text/text-idx?c=ecfr&rgn=div5&view=text&node=14:2.0.1.3.15&idno=14#14:2.0.1.3.15.4.9.1
for the actual regulations. These regulations are straightforward and easy to comply with. None the less, there has been some confusion and a certain amount of dis-informatiodisseminateded regarding the FAA's policies regarding unmanned balloon flights in the past. Most amateur groups side step the equipment, notification, and position reporting requirements by operating Part 101-exempt. I.e. with payloads below the limits of 101.1.

*** The UTARC group made an impressive 3300+ mile flight from Knoxville Tennessee to almost Ireland with a small plastic floater balloon.

6065. Floating

Yahoo group: GPSL (2009 — 2010)
Date: 2009-09-21 16:01:43 UTC
From: Jeff Dailey
Topic: 6065 Message: 6065

We have been doing this for some time now, the system is a valve biult into the neck of the balloon. Its controlled over the wireless network from the command POD or it can use its onboard GPS to control the target float atitude and flight time without the command POD. It is programmable through a comm. port connection on the valve unit.

Hi Cait,

? The float valve is self-contained...no wires needed to control it from a lower payload as Mike Manes suggested in his last email. However, I haven't had a chance to test?fly the?latest design of it....I may get a chance to test it out on October 3rd however and can send you the tested version in time for your launch.

? I can program it for a float at about 70k feet....you might also want to consider flying a ballast drop mechanism in case you start dropping too far down during the flight (I'll try to send you a circuit for this soon)....this can?be a simple as dropping off a weight of a few ounces (with streamer) if the altitude gets below 60k feet....I'm going to be at the Digital Communications Conference in Chicago?later this week?giving a talk on telemetry and also am the banquet speaker there. Your balloon?group might be interested in attending this as they will be discussing new digital communications techniques for telemetry as well as digital TV. The SuitSat folks (satellite launched by kicking it out of the ISS in a spacesuit)?will be there as well with their system.

? www.tapr.org/dcc

?Another university group has?contacted me?who is also planning to collect comet dust with Aerogel...they may fly in November.?We did this in the late 90's from Marshall Space Flight Center during the Leonids meteor storm. The trick is to uncover the Aerogel in the stratosphere and then recover it before balloon burst.

- Bill

Hi Bill!

I think we'd like to use the valve method you described. Professor Flaten mentioned it a few weeks ago but wasn't exactly sure how to go about implementing it. I'd like to take you up on your offer for the valve and more info; the launch is scheduled for October 10th. Thank you so much for your help; the whole team really appreciates it. Have you had any new and exciting ballooning adventures since we last saw each other? Talk to you soon, Cait

?

Hi Cait,

?

? I have done three different methods for floating a latex balloon. The best time for a longer duration float is to launch a couple of hours prior to sunset and then valve off the excess helium lift before reaching the burst altitude. I recommend about 70,000 feet since that puts you into uncontrolled airspace and in the minimum wind field?as well.

?

? A daytime floater can last up to 6 hours but runs the risk of latex degradation by the UV radiation... .I've had over 20 hour floats when running the mission mostly during the night.

?

Here are the three methods that I've successfully used so far:

?

1) Constant pinhole leak.? I use a piece of plastic conduit pipe with a 1/16" hole in the endcap that fits in the balloon nozzle....the UK group has also tried this by punching a pinhole directly into the balloon nozzle....but the hole size could vary using the UK method as things stretch out a bit....but they have successfully achieved float this way as well. The only part is that it?is not fullproof as you are actually floating at the burst altitude.... it's about 50/50 whether it floats or bursts...if you get the pinhole a bit too large, then it won't even reach burst altitude and will slowly come back down.? In my flight tests last year, a 1/16" hole flown overnight floated between 98,000 feet to 107,000 feet for almost 17 hours. However, when I tried two 1/16" holes it only went up to 28,000 feet and came back down.

?

2) No vent/No pinhole float:? Precisely measure lift such that at balloon sunset the loss of solar lift equals the positive lift that you put in at launch....requires you to make sure the balloon is ascending at such a rate that it doesn't reach burst before sunset. I've done several 20 plus hour flights this way....need to keep the positive ascent rate below 300 ft/min for maximum chance of success.

?

3) valve system.? Best reliability and controllability. ...but requires an active servo system to remove a ball from the end of the plastic pipe to vent helium. With a ballast system, you can steer up and down a few times with this method. I can send you photos of my vent valve that plugs in the balloon nozzle when I get back to my house.

?

Hope this helps....will be glad to send info and a valve to you for a future flight.

?

For longer flights, you'll have to go to a plastic zero pressure or super pressure flight...the super pressure flight is extremely tricky to get the exact amount of helium

just right. I've been involved with many of these kind of flights and can help out if you decide to go this route.

?

- Bill Brown WB8ELK

Hi everyone,?

I hope things have been going well since the conference! The U of M Ballooning Team is getting some new projects ready for flight, but we need to float our balloon at altitude, something we have not done before. How do we go about doing this, and what is the best floating method? Any advice would be much appreciated.?

Also, I remember reading that the BLAST! video could be requested by groups from the GPSL conference- who do I need to contact to find out more about this? Professor Flaten is teaching a freshman seminar this semester and would like to show the movie to his students.?

Thanks so much!

Jeff, Jeff... you're killing me here... LOL.

In the future please use; http://www.arhab.org/annomail.html to submit your flights, you can do up to 3 flights on one note. It would really help me out a lot of you did it that way.

I have what you've sent posted, but take a look and let me know. Your dates inside the note don't always match the subject of your notes, I think I used the subject note for all of them.

"Pigs in Space", excuse me for abusing the "Muppets Show", scheduled launch on Saturday evening (Oct. 3).

http://www.balloonfiesta.com/content/2009-schedule

Saturday evening (Oct. 3) will be the first attempt to launch the Gas Balloons from the Albuquerque International Balloon Fiesta.

Watch for the APRS beacons from Balloon Fiesta Field on Oct. 3 around 6 PM MDT.

35.190385,-106.598554

The KB5GAS Repeater is available on IRLP, Node 3676 . Please, respect the wishes of the Pilots when monitoring the repeater.

We recovered the flight, but ti flew about 20 miles farther than we predicted. The GFS model was predicting winds below 100 mph yesterday (as I recall), but we got into a 111 mph jet.

Add to that, that there was a race at the Kansas Speed Way and a KSU game near KC. The last two miles of the turnpike was at a crawl. It's awful to watch your near spacecraft make distance on you.

I saw too many dropped packets on the MT-300 based trackers. I need to look into their datasheets. I want to make sure there isn't something in their design that I'm not taking into account.

All,

There are only 2 reasons that the captcha image would not appear.

1) NOAA is busy/down.
2) The user didn't enter a a wx station that is on the list.

That's the only 2. Really.

As for IE, it works for anything from 6.1 on up, (though I highly recommend ditching anything less than ie-7)

The fact that he can't get it to work on multiple operating systems confirms reasons 1 or 2 above, with a probability approaching unity for #2.

6088. Inventek GPS losing lock at burst.

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-04 17:34:08 UTC
From: lpcoates
Topic: 6088 Message: 6088

Hi Everyone

We fly two trackers in our payload and one is a home built unit built around the Inventek GPS chip and active antenna. On our last two flights, we've noticed that the GPS loses satellite lock a few seconds after burst. Considering the violent motion, this isn't too surprising but we expected that it would recover quite quickly. On SABRE-7 it never regained a lock and claimed that the altitude had stayed at 105,000 feet all the way to the ground and the lat/lon coordinates were at least 10 km off. On SABRE-8 it did the same again but this time it regained lock after about 10 minutes into the decent. I was just curious if others had seen the same symptom.

Did you have the altitude filters turned off? I'm trying to integrate this GPS into my BeeLine transmitter (for rockets), and have seen weird behavior with rapidly changing altitudes on SiRF chipsets before -- I'm hoping that by turning off some of these filters it will behave better.

A question for you regarding the Inventek modules -- have you tried to switch between Binary and NMEA protocols on the same channel?

Hi Bruce,

? I've flown over a dozen flights with the Inventek module so far.. the Sarantel active helix antenna seems to provide the best performance....but I've also flown it with some active patch antennas.

? For the majority of these flights, I've seen great results, often reaching 10 satellites even after burst.....there was one flight where I was testing out a small?patch antenna that was only tracking about 4 or 5 satellites throughout the flight?that had a dropout for a minute or two?after burst but it quickly regained lock.

? How many satellites do you see tracking during your flights?...if it's down around 4 or 5?satellites, then you may have an antenna issue with the GPS.

? The other thing you can try is to put a backup coin cell?battery on the battery backup pin.

Hi Greg

I'm not exactly sure what you're referring to when you mention turning the altitude filters off.

We haven't tried to do any reconfiguration of the GPS at all. We're just using the factory settings.

There are a number of options available when you talk to the device using the SiRF Binary protocol that you don't get to play with in NMEA mode.

Using SiRFDemo, select Navigation->Mode Mask and change the "altitude hold mode" to "disable". The default is set to "automatic". I haven't been able to try it out. One of the problems is that it will reset to the default mode if it loses power on the battery backup pin.

We flew a side-by-side comparison using the EM406A and a Trimble Lassen IQ a year or so ago. The EM406A had a horrible time reporting the correct altitude in a rocket flight to 45K AGL, but the Lassen IQ tracked just fine. (the Lassen IQ also had it's altitude filtering disabled).

I'm hoping that the altitude filtering helps on the Inventek part.

Topic: 6088 Message: 6093

Hi Bill

We're seeing between 8 and 10 satellites before burst. After burst it fluctuates wildly claiming between 0 and 8. Once things settle down and it regains a solid lock, it sits between 7 and 9.

We're using a supercap on the standby line. I know that's working because I can remove the power and it will regain a fix in just a few seconds after powering up again.

We're connected using the tiny RF connector on the unit. I wonder if our antenna connection is being disturbed during all of the post burst tumbling and shaking. I may just wrap it up in some foam and play football with it for a while to see what happens.

At GPSL you mentioned where you were purchasing you antenna from but I can't find my notes about it. Where was it again?

Thanks

Bruce

For the majority of these flights, I've seen great results, often reaching 10 satellites even after burst.....there was one flight where I was testing out a small patch antenna that was only tracking about 4 or 5 satellites throughout the flight that had a dropout for a minute or two after burst but it quickly regained lock.

How many satellites do you see tracking during your flights?...if it's down around 4 or 5 satellites, then you may have an antenna issue with the GPS.

The other thing you can try is to put a backup coin cell battery on the battery backup pin.

Subject: [GPSL] Inventek GPS losing lock at burst.

Hi Everyone

We fly two trackers in our payload and one is a home built unit built around the Inventek GPS chip and active antenna. On our last two flights, we've noticed that the GPS loses satellite lock a few seconds after burst. Considering the violent motion, this isn't too surprising but we expected that it would recover quite quickly. On SABRE-7 it never regained a lock and claimed that the altitude had stayed at 105,000 feet all the way to the ground and the lat/lon coordinates were at least 10 km off. On SABRE-8 it did the same again but this time it regained lock after about 10 minutes into the decent. I was just curious if others had seen the same symptom.

All,

There are only 2 reasons that the captcha image would not appear.

1) NOAA is busy/down.
2) The user didn't enter a a wx station that is on the list.

That's the only 2. Really.

As for IE, it works for anything from 6.1 on up, (though I highly recommend ditching anything less than ie-7)

The fact that he can't get it to work on multiple operating systems confirms reasons 1 or 2 above, with a probability approaching unity for #2.

Hi Greg

Ok, what I see is making sense now. I'm not sure what effect turing this off would have though. If it's having problems aquiring satellites would it sitll not have problems reporting altitudes? My thought is that it would simply report something else that still wouldn't be a meaningful. Or am I misinterpreting what this setting does?

Thanks

Bruce

Subject: [GPSL] Re: Inventek GPS losing lock at burst.

There are a number of options available when you talk to the device using the SiRF Binary protocol that you don't get to play with in NMEA mode.

Using SiRFDemo, select Navigation->Mode Mask and change the "altitude hold mode" to "disable". The default is set to "automatic". I haven't been able to try it out. One of the problems is that it will reset to the default mode if it loses power on the battery backup pin.

We flew a side-by-side comparison using the EM406A and a Trimble Lassen IQ a year or so ago. The EM406A had a horrible time reporting the correct altitude in a rocket flight to 45K AGL, but the Lassen IQ tracked just fine. (the Lassen IQ also had it's altitude filtering disabled).

I'm hoping that the altitude filtering helps on the Inventek part.

If it's a problem acquiring satellites, then no, this won't help. If the problem is that you DO have lock, yet the altitude doesn't appear to be reported correctly, then this may help. Speculation only based upon my previous experience w/ the EM604 and the Lassen IQ.

A few weeks ago, I sent out some misconfigured Trimble Lassein IQ units. They dutifully reported the ground altitude for the duration of a rocket flight to 8000' AGL and back. No change in altitude was ever reported. For the Trimble, at least, if you don't change the altitude filters, it attempts to discard rapidly changing elevation reports.

6098. BASE 40 - Go for 8 October 1210 UTC (8:10 Eastern)

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-08 01:54:00 UTC
From: BASE
Topic: 6098 Message: 6098

Dear friends,

The 40th flight of the BASE program is ready for Wednesday morning at 1210 UTC (8:10 EDT) from the football field at Greencastle High School. Assuming we miss the stadium lights, the burst altitude will be around 80 kft with landing near Cambridge City, Indiana. Downrange 92 miles at 81.3 degrees in 82 minutes!

Flying the geiger counters, LED photometers (inspired by Forrest Mims), digital video cameras, and tilt axis sensors. Radios include APRS (call sign W9YJ-11) every even minute plus 45 seconds on 144.390 MHz (WIDE 2,1) and DominoEX 22 speed on 146.565 MHz (call sign N9QGS) transmitting on every minute for 20 seconds.

Hope to get up and down and recovered before the heavy rains arrive.

Thanks for your support,
Howard

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=370271664154

While not explicit on the label, it has the code "J352-4" on it, which through a Google search seems to indicate a 600g balloon. Seller asking $20 each with free shipping, more than 10 available. Manufacturing date is Feb 2009. Photo on the listing doesn't indicate any discoloration from improper storage. I need to check my stock at home, but I may get a couple myself.

6102. BASE 40 completed

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-08 21:43:24 UTC
From: BASE
Topic: 6098 Message: 6102

Dear friends,

BASE 40 was successfully completed today.

Launch was about 8 minutes late in a light rain.

Launch at 1218 UTC from southwest corner of track around football field. Had good visual of the ascent for nearly ten minutes.

Burst at 88000 feet at 1319 UTC (average ascent speed of 1440 ft/min). Occurred over the southwest corner of Greenfield, IN.

At 62000 feet at 1323 UTC a catastrophic event occurred during post-burst chaos. The APRS unit remained attached to the parachute, but one of the swivel connectors opened and the remaining string was cut by the carbon fiber tube released the 900 MHZ command pod, DominoEX, geiger counters, video cameras, and photometers. With no chute, these boxes landed in a field southwest of Knightstown and northwest of Carthage, IN. Impact occurred at 1334 UTC and the flight data recorder indicated a speed of about 48 miles/hour 200 feet above the ground. Maximum descent speeds in the free fall reached 120 miles/hour.

With the reduced load, the parachute and APRS unit landed east of Richmond, IN at 1410 UTC in a soybean field about 2.5 miles east of the Indiana-Ohio state line between US 35 and I-70.

I will examine the video for additional details on the separation event. This initial analysis comes from flight data and analysis of the payload strings.

Thanks again for your support,
Howard

P.S. - I know that Bill Brown would appreciate any feedback from those that attempted to receive the Domino EX signal.

Unless I'm missing something, I don't see any spec that states these are 600 gram balloons...just looking at the photo seems like it's smaller than a 600 gram envelope....going by the standard burst altitude chart on Kaymont's website....the closest one to 26KM burst?with their standard radiosonde weights would indicate that these may possibly?be their KCI 350 balloons.....i.e. 350 gram size....although it would be a

- Bill WB8ELK

Anyone else have a better guess?.....can't find any details on the government stock numbers that say anything else but 26KM.

I finally found it:

http://www.geo-nwsjan.msstate.edu/docs/chapters/Chpt-10.pdf

Page 10-10 does indeed state that the GP26KM is the new designator for what used to be called a 600 gram balloon.

So this does seem to indicate that these are indeed 600 gram balloons which is a good deal.

6114. ARBONET 3 Set for launch at Clarksville Airport October 17, 2009

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-14 21:03:51 UTC
From: Michael
Topic: 6114 Message: 6114

The ARBONET team is planning to fly ARBONET 3 on October 17, 2009. This date was chosen to coincide with JOTA, an event where Boy Scouts nation wide (and even International) utilize Ham radio to exchange hello's and information about themselves and their troops.

We will be flying four payloads this trip, the voice beacon and APRS unit in Payload 1, (we still expect the woman in the payload to get lost again)! In payload 2 and 3 we will have APRS and Cross-Band Repeater as well as cameras, and Payload 4 is a guest payload with a 20M CW beacon from the Richardson Wireless Club.

Liftoff is scheduled for 9:30AM. See http://www.arbonet.net for more details.

Best Regards!

--Michael K5NOT

6115. Salina Launch

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-15 13:01:51 UTC
From: L. Paul Verhage
Topic: 6115 Message: 6115

I didn't see a link to the online reporting system, so let me pass this on now. Keith, can you email me the link again?

I'll be launching a balloon with Pete Sias and KWU in Salina this Saturday. We may actually launch two of them (there's enough payload). The trackers I'm sendng up will transmit on 144.39 under the callsigns, KD4STH-4, -8, and -9. The balloons are 1500 gram.

Launch takes place from the KWU campus at 8 AM this Saturday. Current trajectory is towards Wichita, but the winds aloft report I looked at didn't go all the way to 95,000 feet.

Zack, we may not be too far from your location. Do you want to help with chase?

From: Rodney Sparks
Topic: 6117 Message: 6117

Hello all,

I've fairly recently discovered the hobby of high-altitude ballooning, and have yet to do my first launch. I'm having fun in the planning stage at this point. ;-)

While looking around on the web, I didn't find an online forum on the topic of high-altitude ballooning (and I didn't know about this list until Paul Verhage pointed me here). I've created a web-based forum at http://www.nearspace.org for the discussion of high-altitude ballooning and all of its facets, including telemetry/tracking based on amateur radio, ISM bands, cellular networks and/OR completely GPS-based solutions (Find Me Spot tracker). I find web-based forums to be a really slick medium for online communities, as a person doesn't have to read about topics in which he isn't interested, but can if he so chooses.

I'd like to extend an invitation to any and all of you who are interested in participating in discussions over there. I plan to be active on this list as well as on the forum. My desire is to bring people together that may or may not have started out as amateur radio operators, but rather could have started out with simply the desire to send a payload into near space and prove to themselves that the world is indeed round, using any and all technology available to do it in the slickest/cheapest/coolest manner possible. The success of a web-based forum, as with an e-mail list, depends greatly on the "technical backbone" of subject matter experts that share their experiences and guide newbies in the right direction, and I hope that some of you are itching to find an additional portal through which to share your passion for ballooning.

Whether you participate or not, I'm also interested in any and all feedback with regard to how I have the site set up, etc... I want this to be the best it can be for the hobby. I've experienced several very successful web-based online communities, such as MegaSquirt EFI (www.msefi.com), and am very optimistic about what it can do for this hobby in this increasingly tech-savvy world.

Respectfully yours,

-Rodney Sparks

I'd love to help chase, but I have to work this weekend until noon, and don't have a way out at this point. I'll pass this along to Jon to see if he wants to go.

I'd be available after noon if you're having any recovery issues.

6119. Saturday's Launch

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-15 17:24:01 UTC
From: L. Paul Verhage
Topic: 6119 Message: 6119

I've updated the webpage with launch information. In case you don't see it, the trackers going up are N0OY-11 and KD4STH-9 (and probably also -8 and -4). N0OY-11 is transmitting on 144.34. KD4STH is transmitting on 144.39.

The flight is for Kansas Wesylan and KU. I'll be curious to see how well KD4STH-4 comes through, it's the lunch bag tracker with a MT-300 and dipole made from 12 stranded wire.

http://www.9news.com/news/article.aspx?storyid=125161&catid=339 (pics of the balloon on web site)

[I'm worried for the kid, but at the same time, envious...]

LARIMER COUNTY - Officials in Larimer County are actively searching for a child who literally floated away from his family's home on an experimental aircraft.

According to the Larimer County Sheriff's Department, the 6-year-old boy's family had been building an experimental aircraft which had a large helium balloon attached at their home on Fossil Ridge Road in Fort Collins.

On Thursday morning, according to the family and officials, the boy got onto the aircraft and detached the rope holding it in place.

The aircraft is described by the sheriff's office as a dome-shaped, 20 foot, 5 foot aircraft covered with foil.

Viewer Lisa Eklund sent photos of an aircraft in the air near her home on Saturn Drive, also in Fort Collins.

The Federal Aviation Administration is working to track the aircraft on its radar tower and has notified the Denver International Airport.

Shortly after noon, the Weld County Sheriff's Office says the boy was lseen two miles south of Evans, near County Road 46 and Highway 85. Sky9 is now helping track the aircraft.

9NEWS and Sky9 are following this story and will continue to provide updates as they are available.

I feel it's far too small even to lift a child this small.

Plus, ummm, why doesn't anyone talk to the parents yet to see where the kid is?

Excellent point! If the dimensions quoted are correct (20 ft dia, 5 ft thick), that's only a bit over 300 cu ft. That's what, about 16 lbs gross lift? This is simply figuring on a cylinder of that size - a saucer shape would be less (think round Mylar balloon on its side).

Dimensions of 30 x 8 would roughly double the lift figure, still marginal for a 6-yo (mine weighs about 40 lbs and she's small for her age). From what I remember of the landing footage and the people next to the balloon, 30x8 may be closer to correct.

The thing with the parents is odd - seems the authorities are closed-mouthed about that at the moment.

The next question is now,,

I know of a few groups (Mine included) that have had rouge flights, but they really didn't cost anyone anything other than time reporting where it is for a long time.

Now this though,

we got Black hawks, other copters, we have ground earch and rescue people. etc. what a simple Medivac flight costs, this will have to cost maybe 100 grand on costs to the state governments/ are they going to be liable for this? especially no one knew or knows where the kid is?

Worst case I can see is, if it was possible to take off, sadly he fell out sometime during the flightand thats why no one is saying where he is, because they simply don't know where the body is.

BUT, still i think it was too small, and as soon as i seen the footage on TV while it was flying I was like 99% sure there was nothing in the "Gondola" for several times that thing almost turned up side down while it was flying.

If it had a 40 pound ballast weight in it, there would be absolutely no way the thing could almost flip up side down like that.

6125. balloon mystery deepens

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-15 20:24:17 UTC
From: Mark Conner
Topic: 6125 Message: 6125

Attached is a screen shot of the balloon at landing. The picture is distorted as it's a video capture, but even so you can see there's almost no way the balloon can be more than 6 ft top to bottom and is 25 ft in diameter if one is generous. That puts an upper bound of about 470 cubic feet, for 30 pounds of total lift.

The boy never left the ground.

One other "duh" observation just occurred to me. If it were big enough to get the boy off the ground and he fell out, the 40+ pounds of free lift would have rocketed the balloon out of the troposphere at a pretty good ascent rate - it wouldn't become neutrally buoyant at a few thousand feet AGL.

So, did you guys see the black and yellow "static sensitive" stickers around the periphery of the balloon? Based on that, I'd say it might have been filled with hydrogen, not helium. That's only about 8% more buoyancy though.

I figure that if that balloon had 40 pounds of ballast on it and then lost that ballast, it wouldn't have stopped ascending at ~8k ft like they said it did, unless that drooping side of the balloon had a tear in it and most of the gas had escaped along the way somewhere.

This is getting weird.

Ok
I'm making assumptions here say he did have it fully inflated so it looked right. Nice flying saucer shape. and that it did have enough lift, assume it did get airborne, with the boy (hope not) but say it did, and the loweer part of the gondola did fall off, Like others have said it then would have taken off like a rocket, BUT, having such an excess amount of lift of course it would pressure that envlope quite quickly since it was probably pretty full already on the ground, not too much altitude and i would think it would have tore open a seam, which it probably did because of the one side that was not inflated anymore because that area had the tear.

Now a question to the EOSS guys,

have any of you tried to run a flight profile of this thing and possibly offer it to the authorities for the possible flight path it might have taken? i don't know if anyone in the search and rescue field would have programs for predicting flight paths like this or not.

might be nice to just offer it?

maynbe?

Joe

The forecast wind profile was pretty unidirectional from the northwest from surface to about 15,000 MSL. I'd bet it didn't go more than a mile or two either side of a straight line from launch to landing.

Also, if you watched the rescue crew at the landing, no one searched the gondola right away, so I think they knew he was not aboard even before it landed. Their main concern was keeping the balloon on the ground.
Something is up.

Listening to the scanner, the responders were told to be cautious of the envelope and anything silver
as it may have a 10,000 volt charge on it. Apparently some part of the science experiment that the
balloon was intended for. They were told to look for something on the side of it to indicate zero before
handling it. Hence the caution, slowness to jump on it.

CNN is talking to the sherriff people, and they are searching the area directly easdt of the launch site.

They say it landed southeast, but they say it could have taken a path that could be anywhere from due east to due south than drifted to the south east.

wow. they do not have any idea as to the path this thing took.

How are you guys coming up with a volume under 500 cubic feet? If you base this on a simple cylinder, then it's pi*r^2*length. If it's 25' in diametre and 6' tall, then it would have a volume of almost 3000 cubic feet.

I came up with 1040 cubic feet.....volume of an ellipsoid that is 20 feet in diameter and 5 feet tall....however, comparing the diameter in the field against the height of the responders...it looks closer 14 feet in diameter.

Total brain lock - I was using pi*d*h for volume instead of p*r^2*h. Trying again, assuming a cylinder 20 ft in diameter and 5 ft tall would be 1570 cu ft and that would be enough to lift close to 100 lbs. Bill's ellipsoid model would lift about 65 lbs.

Should have taken a nap instead of committing math on the e-mail list.

I'd love to help chase, but I have to work this weekend until noon, and don't have a way out at this point. I'll pass this along to Jon to see if he wants to go.

I'd be available after noon if you're having any recovery issues.

I'll get the posting started with what you gave me, you can fill in the gaps when you have a minute.

On Oct 15, 2009, at 8:01 AM, L. Paul Verhage wrote:

I didn't see a link to the online reporting system, so let me pass this on now. Keith, can you email me the link again?

I'll be launching a balloon with Pete Sias and KWU in Salina this Saturday. We may actually launch two of them (there's enough payload). The trackers I'm sendng up will transmit on 144.39 under the callsigns, KD4STH-4, -8, and -9. The balloons are 1500 gram.

Launch takes place from the KWU campus at 8 AM this Saturday. Current trajectory is towards Wichita, but the winds aloft report I looked at didn't go all the way to 95,000 feet.

Zack, we may not be too far from your location. Do you want to help with chase?

Joe's correct.

And that's basically what I told the reporter from CNN who called to ask my views. At the time, all I knew was from the Ch 9 news 'copter reports, and told them that a balloon that shape made of aluminized mylar would have to be about 100 ft in diameter to carry a 70-80 lb kid. Once the actual size was reported, I knew it never would have gotten off the deck with that much weight.

Friend wife told me that the family's going to be on Larry King Live. Much ado, but it could have been pretty tragic if the bag had been a lot bigger.

If the fill gas (and residual air) had completely filled the envelope, then it would have behaved like a super-pressure balloon and floated at an altitude where the weight of the displaced air equaled the total balloon + payload weight (Eureka!). But SP bags have got to be strong, like bull, to hold much pressure, so a seam may have opened up letting the gas vent, and that brought it back down.

Hi Joe,

I didn't learn of it until someone called me on the local repeater, and
by then, the 9 News helo was in visual pursuit. So no, I never gave a
thought to trying to tweak the predict program for that weird config.

Late last night some "Balloon Expert" they were talking to talked about
that balloon. And he said what someone could do with it, and stuff
like that and he had it rifgght too that it's too small to carry a child
aloft and he also said the same thing that if he was indeed in it
somehow it would never fly the way it was turing on it's side at times.

BUT! what I found amazing is that he said the balloon is a Kit you can
buy online.

I never seen anything like that on the web i wonder where and how much?

6143. Balloon Hoax??

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-16 13:05:25 UTC
From: L. Paul Verhage
Topic: 6143 Message: 6143

Here's an article that indicates the whole thing may have been a hoax.

http://thelede.blogs.nytimes.com/2009/10/16/interview-sets-off-skeptics-of-balloon-drama/?hp

What I don't care for is the negative light it could cast on legitimate amateur ballooning.

The media being how it is, trying to wring every story they can out of every newsworthy incident, I wouldn't be surprised if a "How was this hoax allowed to happen?" report popped up in the next few days, possibly addressing the current laws and how the "government should do something so this can't happen again... What if next time the kid is on the balloon???" I think you're right about the negative light, Paul. The fact that balloons such as this one are so foreign to most people will likely serve to take some of the focus off of the simple fact that these people committed a hoax of this magnitude, regardless of the fact that a balloon is involved... If they had shoved a car off of a cliff and then claimed the kid was in the car, the focus would be 100% on the hoax and not the means.

6145. volume of 6 yo boy's balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-16 16:59:19 UTC
From: K. Mark Caviezel
Topic: 6145 Message: 6145

Guys:
I'm glad we re-calculated the volume. yes, lifting a 6 yo boy is within the realm of possibility for this size balloon. And that would require 4-5 cylinders of helium. But it sure is amazing how half the world got punked on this.
Maybe this family of storm chasers will get involved in ARHAB in the Denver area ?

best

- Mark ng0x

6146. Update on Taylor U launch

From: Jeff Dailey
Topic: 6146 Message: 6146

Taylor will be launching two balloons on Saturday at 11:30AM local time.
APRS will be KB9ZNZ-1 and KB9ZNZ-11 on 144.39.
Launch location is on the loop at Taylor University.
12 Primary payloads from the Astronomy and Chemistry groups.
105 Analog inputs and 23 Digital inputs.
Wide range of Instruments: Cooled UV, Solar cells, Three axis accelerometers, Turbulence, Wind shear, Temperature, Humidity, Pressure, Video.

Thank you

I also fly high powered rockets. Each time there is some news story that sheds the hobby in a negative light there are some of the same fears. Nothing ever comes of it, though. While these negative story fears are common I can say with a lot of confidence that nothing will change regarding regs. for balloons (a rather benign hobby, actually).

What these events can do is afford an opportunity for those involved in HABing or other types of ballooning to make some positive news in the local media. Right now is the time to get interest stories 'out there' regarding HABing. Who knows how many people have had their interest piqued by what they saw on TV yesterday in Colorado? Maybe some new HABists were born of that coverage...

If this is a publicity stunt, they will benefit from the well-known observation that no matter whether it's negative or positive publicity...in the end, people will remember their name and will generally forget whether it was negative or positive.....so in the end, they've received a lot of publicity which could lead to positive things.

Good point that now is the time to hit up your local news media for launch events.

It'd be interesting to see if a UFO style balloon like this is available as a kit as was mentioned in a previous post.

Here's my take on what happened after watching the news and some extensive footage and coverage of yesterday's events.

Dad was in their backyard messing with his now filled balloon. It was to be tethered for this flight while one of the kids was videotaping. Dad lets go of the balloon and mom doesn't have a hold of the tether so balloon floats away. Dad freaks out and stomps around the backyard (this is on video shown on MSNBC a few minutes ago). Now I'm supposing what's next but after a few minutes he calls the FAA hoping they can track it so he can find it. That doesn't work so he calls the TV station and asks of their helicopter can help him - to get their interest he mentions that one of the older kids said the youngest son was onboard the balloon and is danger. The TV station jumps on that and now it's on. Dad realizes he'd better call 911 which he does (MSNBC said dad made those 3 calls in that order within 20 minutes of losing the balloon).

Dad was upset his balloon disappeared and dreamed up this scheme to get it back. Obviously he didn't put a lot of thought in it and things snowballed rapidly and negatively. Dad will end up being charged with making a false report at some point and this will cost him more money than the balloon ever did. Restitution could be very expensive!

I'd heard a report last night the young kid hiding in the garage attic had snacks and drinks with him. Whenever I got in trouble and ran as a kid I never thought to take food. I think the kid was told to hide there when this thing blew up so rapidly.

I don't know if I'd call this a hoax as such but a desperate attempt to recover the lost balloon which was really stupid and went way beyond what dad thought it would.

The family was interviewed on both the Today Show and Good Morning America today. The youngster vomited on BOTH shows! He seemed a little stressed to me.

If this is a publicity stunt, they will benefit from the well-known observation that no matter whether it's negative or positive publicity...in the end, people will remember their name and will generally forget whether it was negative or positive.....so in the end, they've received a lot of publicity which could lead to positive things.

Good point that now is the time to hit up your local news media for launch events.

It'd be interesting to see if a UFO style balloon like this is available as a kit as was mentioned in a previous post.

I also fly high powered rockets. Each time there is some news story that sheds the hobby in a negative light there are some of the same fears. Nothing ever comes of it, though. While these negative story fears are common I can say with a lot of confidence that nothing will change regarding regs. for balloons (a rather benign hobby, actually).

What these events can do is afford an opportunity for those involved in HABing or other types of ballooning to make some positive news in the local media. Right now is the time to get interest stories 'out there' regarding HABing. Who knows how many people have had their interest piqued by what they saw on TV yesterday in Colorado? Maybe some new HABists were born of that coverage...

Subject: Re: [GPSL] Balloon Hoax??

The media being how it is, trying to wring every story they can out of every newsworthy incident, I wouldn't be surprised if a "How was this hoax allowed to happen?" report popped up in the next few days, possibly addressing the current laws and how the "government should do something so this can't happen again... What if next time the kid is on the balloon???" I think you're right about the negative light, Paul. The fact that balloons such as this one are so foreign to most people will likely serve to take some of the focus off of the simple fact that these people committed a hoax of this magnitude, regardless of the fact that a balloon is involved... If they had shoved a car off of a cliff and then claimed the kid was in the car, the focus would be 100% on the hoax and not the means.

http://www.thedenverchannel.com/news/21317493/detail.html

According to this timeline, Dad mentioned the possibility of the boy being on board when he called the FAA and the media. However, we all know how often details like this are added or assumed in news coverage.

Dad would also have known if it were plausible for the balloon to lift his 37-lb son. You can tell from the video of the launch it's not pulling up with 37+ lbs of force. He's not a rocket scientist, but I imagine he's worked out that it takes 16 cu ft of helium to lift a pound and how many cubic feet he's put in for this test. There's no way he would have put almost 40 lbs of free lift in the balloon if he just expected to "winch" it out a little, or even release it and have it go a few thousand feet up. Or he's totally clueless. This is one of the few times I go against the dictum "never attribute to malice what can be adequately explained by stupidity".

For the record, the response by the police, FAA, and (to a point) the media was correct given the facts as each knew them at the time. I saw one story where the police did confer early on (first half hour?) with a professor who (correctly) worked out that given the dimensions it was plausible for a balloon of that volume to lift a boy.

Regarding publicity from this event spilling over to ARHAB; I'm not so sure it'd be a benefit. Depends on the reporter I think. They could easily take the tack of "oooh, look, our own local mad scientist - isn't he weird". Dunno if I'd run the risk.

I just wanted to let the group know about the sale going on right now on the SPOT☐ Satellite Personal Messenger like what Bill Brown used during the last GPSL.

Purchase a Spot Satellite Messenger from a participating Cabela's location or Cabelas.com and receive a FREE Spot Messenger (a $149.99 value) or up to $75 by mail-in rebate based on additional purchase of service plan.
Offer good from 09/01/2009 to 12/31/2009.

I've heard some mixed reviews about Spot. Some people love it and others have said it misses too many of the 10 minutes upates. I'm curious to hear other experiences. I'd like to fly one as a backup tracker and write an article on it. But if it misses too many reports and costs $99 for the recever and $99 per yar for the basic service......

6153. SPOT review

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-17 16:39:06 UTC
From: K. Mark Caviezel
Topic: 6153 Message: 6153

Love it!
There are some purists that will decry the non-hamness of it. That is indeed a characteristic of this commercially available hardware and service. But I am really impressed with the performance of the SPOT. I had my SPOT in the glove box of my pickup truck during a drive from Oklahoma to DC and had >95% position report success. I am truly impressed with the power stinginess of the unit: 2+ weeks demonstrated function with two AA batteries. Unlike an APRS beacon which needs line of site to a digi or your own antenna, the SPOT uplinks via the Globalstar satellite system.
Drawbacks:
a). $100/year subscription is a nag if you use it infrequently.
b). position reports are lat/long only. No altitude, course, or speed info.
c). minimalistic display/user interface leaves a bit to be desired.
d). Does not report over 60k feet.
e). The 'SPOT Tracking' mode is an extra $50 a year and only allows 24 hours of tracking before reset is needed. The long endurance and trans-Atlantic ARHAB sub-niche will need a hack to do some button pushing at T+24 hours.

Advantages:
a). Lightweight, < 8 oz with batteries.
b). Excellent performance.
c). Cheap.
d). Excellent quality case- waterproof- and the internal patch antenna is not prone to break or snap off as we often see with 2m ham antennas.
e). Good view factor to the satellites, even if your payload lands in a ditch.

best regards,

- Mark ng0x

I have pressure sensors for the weather station I sell. Would a weather station work for you?

If not, I can sell individual sensors, but have to charge more since I'll have a left over PCB I can't sell.

Hello Ron & Group,

For sensing differential envelope pressure the 841-MPXV7002GP from Mouser will do a good job for you. We used the less-sensitive version on the GPSL 2009 flight and should have flown this one. Your differential is between nozzle pressure and ambient (outside air).

For sensing atmospheric pressure from launch to the vacuum of near space :) the 841-MPXAZ6115APT1 will likely meet your needs by capping off the input port and using the differential between the input port and ambient as the value at launch to the increasing pressure of that port at high altitude. In other words, 0 pounds (ambient)=ground level, and +14.7 pounds would equal high altitude - like 368K feet, though you may have to convert to metric air in Canada. :) I have not tried this unit yet, but thought it would be a fun experiment.

Hope this helps,

The Honeywell ASDX015A24R sensor is a 15 psi absolute sensor. To the best of my knowledge, Honeywell does not manufacture a 5 psi absolute sensor in the ASDX series.

If you did use a 5 psi absolute sensor, you are correct that it would be maximized until you reached about 28 kft.

Howard

At sea level it will measure 14.7 psi absolute. It will drop from there until it reaches 0 in a vacuum.

6159. Limb Sounding

Yahoo group: GPSL (2009 — 2010)
Date: 2009-10-31 16:21:01 UTC
From: L. Paul Verhage
Topic: 6159 Message: 6159
Attachments: 2 described; binary payloads are missing from this source WARC

I'm trying an experiment in limb sounding from near space. This first iteration has acquainted me to some of the problems involved, but will also help me develop solutions. I'm attaching two files, one is an image of the horizon as strips from every 10,000 feet. The second is a chart based on data derived from sampling the colors of the images at 0.5 inch points above the horizon.

The first problem to solve is verifying the camera is pointed the same direction everytime. I've developed a sun sensor that I'll fly on future missions so that the flight computer will only record images when the sun is located in the opposite quadrant. The second part of the solution is to fly a sun compass. The shadow it creates in the images will further refine the sun's position and let me weed out more pictures. The flight computer will be programmed to snap several pictures every 5,000 feet when the sun is located in the proper quadrant. This should give me a large selection of images to choose among.

I need to calibrate angles and fields of view with my camera. Right now I can measure the same elevation above the horizon, based on pixel hieght. I need to convert this into angles so the results are more meaningful.

Third, I'll rotate the camera 90 degrees so more of the image is above the horizon and I can get higher elevation data.

Fourth, I need to understand how colors are converted into values inside an image. I'm assuming things are nearly linear, so I take the values for RED, GREEN, and BLUE (in 8-bit resolution their maximum values are 255), add them together, and then divide each color by the sum of all three colors. The computed value is then divided by 765 (the sum of 255 + 255 + 255), or the maximum value the colors are allowed to have. Perhaps this arithmetic average is not as good as a geometric average. If the colors are considered orthogonal to each other, then it would seem the geometric mean would be more appropriate.

This is what I like about near space exploration. Everytime you look into an experiment, it opens a can of worms of problems to solve. This activity certainly isn't a closed-end experiment like high school chemistry class.

One issue to keep in mind is the exposure compensation the camera performs to adjust the "raw" camera sensor values to RGB. I'm not too familiar with the transformations involved, but a bad choice by the camera could cause misleading values in the RGB result.

It's possible using images saved in RAW format might yield better results, but I'd have to explore that some more. The values might be 12 to 16 bits in depth for each channel. I know the Canon A560 will save in RAW format (at a considerable penalty in file size increase). Picasa now offers (limited) RAW file manipulation. If you know the exposure conditions (aperture and shutter) you may be able to back up from a RAW value to some absolute brightness number in each channel.

From: L. Paul Verhage
Topic: 6159 Message: 6161

I'll look into RAW format. That may be tghe way to go. I have a 2 GB SD
card, so I still should be able to store a lot of photos.

6162. DARPA network challenge

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-02 03:32:39 UTC
From: Mark Conner
Topic: 6162 Message: 6162

A rather interesting contest. First prize is $40,000.

73 de Mark N9XTN

http://networkchallenge.darpa.mil/

To mark the 40th anniversary of the Internet, DARPA
<http://www.darpa.mil/>has announced the DARPA Network Challenge, a
competition that will explore
the role the Internet and social networking plays in the timely
communication, wide area team-building and urgent mobilization required to
solve broad scope, time-critical problems.

The challenge is to be the first to submit the locations of ten moored, 8
foot, red weather balloons located at ten fixed locations in the continental
United States. Balloons will be in readily accessible locations and visible
from nearby roadways.

6163. Re: [GPSL] DARPA network challenge

Hi All....looks like we should all team up as a "social network" and win this thing!!!

My guess is that many of these will be located near military bases where many of us work....the trick is to tell them apart from car dealership balloons.

My thoughts are that we (ARHAB enthusiasts) probably won't happen to be next to all of the balloons. But that's not to say that you won't happen to know (or be on Facebook) with someone who is near it, and therefore can get/provide the Lat/Lons.

I sent the MIT students a payload for their flight on Nov 4th.... about 10 milliwatts on both bands as follows:

144.36 FM - WB8ELK RTTY 45 baud (both modes vertical)
144.357 SSB - Hellscreiber (Feld-Hell mode)

433.95 AM - DominoEX16 (horizontal)

Launch time: 6:45 am EST November 4th

location: most likely from K2CBA QTH in Petersburg NY east of Albany NY:

Predicted landing zone: between Nashua NH and Haverhill, MA

Please send any reception reports to: wb8elk@...

That would be cool. I guess what is needed is a representative that represents GPSL and takes the reports from members to submit the locations and gain the prize on behalf of GPSL. Money to be used to host future GPSL events.

I'm not completely certain what qualifies as an amateur payload, since some of the participants are enrolled in an academic class taught by university professors. The USI flight was their third. The flight contains payloads designed and built by students. They did carry a APRS beacon operating on 144.39 MHz with callsign W9MOK and the flight path was on the internet. [You can still see the track on aprs.fi/?call=W9MOK]

They have a website: http://web.usi.edu/HAB/

USI is one of the schools that has begun an academic ballooning program after participating in a National Science Foundation workshop at Taylor University. Some of these programs actively share information via a social network at www.nearspacenetwork.com

6181. Payload inversion at high altitudes

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-09 19:57:07 UTC
From: BASE
Topic: 6181 Message: 6181

Dear friends,

I have learned of a recent high altitude balloon flight (my son had a experiment on the flight) where during ascent, the payload string was inverted above the balloon and parachute above 80 kft. Has anyone else ever experienced this phenomena?

The video evidence includes a photo taken at the moment that the payload box with the camera fell down through the balloon causing it to rupture.

Just curious if this has happened to anyone else.

Howard

We've seen several pix from our flights where the parachute appeared BELOW the horizon, and that's one form of Post Burst Chaos that many of us have experienced. However, I can think of no mechanism that would cause the payload string to rise above an ascending, inflated balloon envelope.

Common PBC is likely the result of a severe form of parachute instability, causing the parachute to be pushed sideways due to high-velocity lateral venting. And parachutes don't work all that well flying sideways. So a payload that has a low ballistic coefficient (low terminal descent rate) can have more drag than the compromised 'chute, thus causing inversion of the entire string.

We had one case where part of the payload string fell into the top of the parachute canopy, causing a rather snappy 15-minute descent from 95K' with an abrupt halt on a plowed field well short of the predicted downrange point. JPL had the same thing happen with a much heavier payload that left a prominent divot in the desert.

Are you SURE that the balloon was still inflated on iversion? I just watched the CNN video, and saw a normal burst, with gobs of latex shards hanging off the top of the parachute - which also execerbates the 'chute instability problem, BTW.

We've also had some poorly-attached student payloads become detached during PBC - and in one case, it was a string of 6 shoe box sized and very light ones that severed a 240 lb tensile Dacron line. We did find 'em within a mile of the burst lat/lon the next day - but only with an air search. We haven't used Dacron since then, because it doesn't stretch nearly as well as woven nylon - the latter acts like a bungee cord, thus spreading impulse shock over time and distance.

Hi Howard!

Did you look for little green fingerprints on the payload? Perhaps ET was at play here? :)

Curious - What was the weight, size and shape of this payload?

Reading your message I assume you meant "visual evidence" and not "video evidence", and you have only a single picture of the inverted phenomena? Were there other pictures on the way up that would indicate severe turbulence?

My thought - there must have been a high-altitude wind rotor event which flipped the whole mess. The YF-12A and other planes that have flown at 70-80K feet have encountered rather strong turbulence at these altitudes, though it occurs in only a small percentage (4-6%) of their flights. These can be caused by terrain disturbances or more likely pressure gradients creating tucks and swirls in the layers of the upper atmosphere.

My two recent videos at high altitude showed only a very, very calm atmosphere up there, as if the payloads were hung from something on solid ground. There was not a hint of any turbulence. No doubt there is drastic movement up very high as well at times, we just don't see it often.

6185. Re: [GPSL] Payload inversion at high altitudes

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-10 01:03:21 UTC
From: BASE
Topic: 6181 Message: 6185

Dear friends,

The flight that I am referring to has nothing to do with the University of Southern Indiana flight that made CNN. The payload inversion occurred on October 17, on one of the Astronomy class balloon flights from Taylor University. The balloon was a 1500 gram with a helium fill and approximately 11 pounds of payload in at least nine payload boxes. The ascent rate was approximately 1400 feet/minute.

Although I have only seen several screen captures from the flight, the evidence is indeed video from two video cameras one mounted looking up the payload string and the second looking down the string. The first two images that I have seen shows the payload string nearly parallel to the horizon at about 82,000 ft. The image at 82,500 feet show only contain a couple of pods at odd angles. The next two frames that I have seen are labeled at 82,625 feet and show the parachute, spreader hoop, and slack payload strings on top of the balloon.

The balloon is clearly inflated until the last two screen captures that I have seen which show the camera pod moving through the balloon. The last image shows the artificial curves in the clouds due to the rapid tumbling that occurs so often in the post-burst environment. These last images are all identified at the same elevation and may be consecutive frames from the video.

Like Mike, I have seen many minutes of post burst video with inverted stacks of payloads and various rearrangements of payload order including slack line between boxes and the parachute and balloon 'leading' the descent. These photos are remarkably different.

It has been suggested that the phenomena may be a result of high altitude clear air turbulence such as may occasionally be encountered by the U2 and ER2 aircraft. See:

We would really like to see this video/still imagery. EOSS's vp is a NOAA guy and wants a peek too.

Do you have links to the pix from the Taylor flight that you could post?
I'd love to see what you've seen!

6196. Iowa balloon flight Thursday

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-14 00:40:13 UTC
From: Al Wolfe
Topic: 6196 Message: 6196

Yesterday KC0GBP-11 flew in NE Iowa to something over 100k altitude. Congratulations on a good flight guys!

However, the ten second packet rate on APRS was a bunch over the top. And that with a path of Wide2-2 pretty much tied up and saturated the APRS network in several states for a few hours.

Gotta be a better way.

Al, K9SI

6197. Iowa balloon flight Thursday

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-14 03:20:09 UTC
From: Pete Lilja
Topic: 6196 Message: 6197

Hi, Al,

Thanks for the kudos on the flight. It was a wild one for us to be sure.

It has been discussed on one of these balloon lists about the flight and particularly the overwhelming number of packets thrown by our (my) radio on this flight. It turns out I had the profile switching in my Open Tracker + activated above 50,000' when it switched profiles and sent a packet. It then switched to the original profile and sent another packet. I see now the err and have and again apologize to the APRS community for jamming and abusing the network. While unintentional this was entirely my fault. I know now what to change .

As is often the case I learned more from the mistakes on this flight than with what went right. For me that's what this is all about. I do regret, however, the radio bungle as that affected a lot more people than just me and the NIXHAB group.

106,000' was a huge surprise. As I never thought I'd do I was wishing for an early burst as that balloon slowly rose above us. But that didn't happen. My balloon buddy, Larry, commented at one point as we sat in my car 20 miles below the wildly transmitting payload in his stoic and laid-back way - "A watched balloon never bursts." Now, I don't care who you are that's funny.

I am sorry this has happened and will work to see that it doesn't happen again.

Pete

That has already been covered in another discussion... :) I am not sure if the balloon actually hit the ground yet and major flames were flying about the APRS issue.

There was a malfunction in their APRS beacon, it was at 1 minute intervals prior to 50K feet then went into another mode or configuration automagically. They are looking into it.

Yes, in digi-populated areas nothing for a path will work in many cases, or today Taylor flew with Wide1-1 and that seemed to work well. It was pointed out that the worst case for an AHAB is Wide2-1.

Unfortunately in-depth info on when to use what setting in APRS is really not widely published. I have not found anything about path setting of APRS and ballooning in my quick searches on the net. I think a lot of us could have put in that same setting being new to APRS without a second thought, as it's impact is not obvious until the affect was realized.

I will add a note on my website (ARBONET.NET) to hopefully help in this regard. If anyone knows of good links that I missed that details APRS and AHAB, I would love to add them as a link from our site.

I am certain several of us learned a lot from that flight. I appreciated that someone else had a better flame suit on for something I might have done too! :)

From: Pete Lilja
Topic: 6196 Message: 6199

Well said, Michael. Thank you. Being the offender here I would welcome this discussion.

I know it comes up from time to time the 'proper' APRS settings for HA ballooning. What I've seen and gleaned from those discussions is that there is no real consensus. Everyone has a different opinion from differing backgrounds, experience and geographic locations.

Here in NE Iowa there are relatively few digis. That's not a problem a few thousand feet AGL but can be while the radio rests after landing. I only realized tonight that the last packet made to the APRS network was digi'ed through *my* mobile as we got close to recovery near Dubuque. (Dare I say it? I thought I'd turned off my digi! Another radio mistake by me yesterday that turned out to help me). I was wondering how that packet made it out as the antenna coax cable pulled free (I believe from the online look of the descent) during PBC.

At any rate - APRS transmission settings. What should they be? I'm now running an Open Tracker + with the advantage of changeable profiles. Can I (and should I) have it beacon a Wide 2-2 only below, say, 3000'? Over that use a 1-1? Or what?

What about those that fly radios without Profile Switching? Should they not be allowed certain settings that may help them with recovery?

I am in no way proposing any 'rules'. But maybe some guidelines that can be used for various set-ups and geographical locations to help people decide what will work best for them and the APRS system..

I can take the flames, lumps and hits for this. I'm learning a lot from the flight.

And I will add that with the one glaring exception I have received many, many words of encouragement and support from the ARHAB community despite my faux pas yesterday. To me that is a testament to the quality of people that participate in this hobby.

Since the discussion on APRS radio settings is an important topic to me (and others, I'm guessing) I've begun a new topic on the subject on the forum at http://www.nearspace.org/forum/index.php I find these forums a convenient place for this kind of thing as the topics are all contained in one area as opposed to these emails that get lost and wander topically.

Please join in and chime in with your ideas.

From: Al Wolfe
Topic: 6201 Message: 6201

Pete,
I was not able to stay around and watch your whole flight Thursday but it looked interesting to get up that high.

As far as your APRS path I don't know what would be optimum. Wide1-1 will key up almost every APRS station within range which can be several hundred miles at altitude. 2-1 will only key up the digis. Probably no path at all would be fine above 20k.

Of course that all changes when you're out looking for the package on the ground. Here a path of 1-1, followed by 2-1, or an even greater path would certainly be valuable to the searchers and would be a minimal impact on the rest of the APRS network.

I'm not familiar with your hardware but it sounds like some of the configuration can be altitude dependant.

I also have not followed this thread on other Sigs as there are only so many to watch (already get 46 other ones) so don't know what others have offered.

I remember back in the early days of balloon chasing before we had GPS and APRS. That was a challenge!

73,
Al, K9SI

Topic: 6202 Message: 6202

I think it's generally accepted that anything more than WIDE2-1 at "high altitude" is not necessary. Because you'll be direct line-of-sight to the digipeater, if the channel is clear you'll more than likely get in. Adding another hop at the periphery of your already-large footprint is unnecessary. One digipeat, however, gives you another shot at hearing the payload data should the original packet get clobbered.

WIDE1-1 in your path at altitude will bring up a lot of home stations and thus a lot of QRM when they all try to retransmit.

At low altitudes, switching to WIDE1-1,WIDE2-1 should get you into a nearby digipeater to help with the end of your chase if you don't happen to be close enough to hear it direct. I might get you a post-landing posit into the network too.

I think a good transition altitude between these altitudes is somewhere around 5000 ft AGL. Above this you probably won't need digipeater help, below it you might. One could argue plus or minus a bit, but that's only a handful of minutes on the network.

High posit rates (more frequent than every minute) should probably be left to a non-144.39 frequency. 144.34 was commonly used earlier, but can draw complaints from SSTV users (it's often used as a simplex voice channel). NSTAR has settled on 144.36 MHz as our high-rate freq.

Thanks, Mark,

That is a very succinct and easily understood response.

Are there any OT users out there that use the profile switching to do as Mark suggests and willing to share their OT+ configuration file with other HABists?

Sorry for the short notice but the MIT students will be flying from Albany, NY Sunday (today) at 11:00 am EST. They will be carrying a payload I sent them on 144.36 MHz FM sending down DominoEX16 mode about every 30 seconds. Predicted landing zone is near the NH/MA border south of Jaffrey, NH.

Please send any reception reports to: wb8elk@... and copy it to yeho@mit.edu

Hmmm ... using a callsign of "FLIGHT", eh? Didn't realize France had
adopted all-alpha callsigns, and this shows that the CEPT mutual recognition
agreement has just gone too far :=P.

It seems that their GPS was giving totally bogus data as well - on the
equator at the prime meridian on the deck?

6206. ARHAB wiki article

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-17 04:06:58 UTC
From: Mark Conner
Topic: 6206 Message: 6206

I was poking around on Wikipedia and wandered over to the ARHAB article and made a couple of minor fixes. I found the stats page for the article and went back a few months to see what our hit counts were like. Surprisingly (to me) there was consistently 5-15 hits per day for much of the year. However, on Sept 14 it spiked to 77 hits, which was when the MIT balloon story came out. Higher hit counts persisted in a decaying fashion for about three weeks and are now back to our 5-15 hit-per-day average.

Don't know if these hits are real users or search engines wandering by. If you want to explore the stats page on your own, you'll need to look at "ARHAB" as that was the article title prior to mid-October.

I see people have been keeping the webpage up to date. I think I'll put a graphic together to illustrate the stack.

I subscribe a Google notice about near space. The number of daily notices was huge during the MIT event. They've tapered off to one or two updates daily.

Hi All,

This was launched by John Powell's group, JP Aerospace from California. They were a competitor of ours during the CATS Prize (Cheap Access To Space) event in the late 90's (our group [HARC] and John Powell's both decided to fly Rockoons). We flew out of the Gulf of Mexico and they flew out of Black Rock. They usually launch from the Black Rock desert in Nevada where this commercial was filmed. It appeared to me that there was no parachute, (you'll note how the chair breaks apart at post-burst chaos), but then nothing but jackrabbits to hit out there...maybe the chute unfurled after burst...hard to tell for sure. This is the same area where the Large and Dangerous Rocket Society have their annual launch and also where "Burning Man" is done...I've attended both. Ask me someday about riding in a car from Burning Man across the dry lakebed back to the LDRS rocket area in the middle of the night at 70 mph with a blindfolded driver relying on me to give him GPS directions to our tent....fortunately it worked and we didn't run over the tent or any rockets....I also somehow managed to survive that experience as well as the two-stage rocket being prepped by the LDRS safety director that accidently fired off horizontally into the parking lot narrowly missing me the following day. It went completely through the back tire of a Bronco....that tire and rocket are still in front of a bar in Gurlock NV at the entrance of the lake.

I also immediately decoded the APRS packets from the commercial and also saw the 0000.00 lat/lons....probably the sound crew just looped the packet sounds since they thought it sounded cool....I could decode it even without an audio filter. If you look at the "Making of Space Chair" YouTube video, you'll see them chasing around with 2 meter Arrow antennas to recover the high def cameras and recorders.

6209. Another flight with pre-burst chaos and pod breaking the balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-18 21:37:52 UTC
From: BASE
Topic: 6209 Message: 6209

Dear friends,

Here is a second HAB flight with pre-burst chaos.

Taylor did a flight on November 12 from Fishers, IN (see ARHAB Balloon Schedule) that experienced pre-burst chaos. Burst was accomplished with one of the payloads.

Two videos and a set of still pictures have been posted on the web at:

PRE-Burst Chaos Down Video -
http://www.nearspacenetwork.com/video/preburst-chaos-vidoeo-111209

PRE-Burst Chaos Up Video -
http://www.nearspacenetwork.com/video/preburst-chaos-vidoeo-111209-1

Payloads Bursting Balloon Frame by Frame -
http://www.nearspacenetwork.com/photo/albums/payload-burst-the-balloon

This is not from the flight of October 17 that Jeff Dailey posted a single frame from recently.

Does the phenomena occur more often when the mid-stratosphere jetstream is changing?

Howard

Wow, that's pretty **** violent for being on the way up.....

For our NSTAR video flights, we've never had anything like that happen. Our still cameras don't seem to show that kind of turbulence on ascent either.

Normally, this level of the atmosphere is pretty benign for turbulence, especially for a scale affecting a balloon (a fast-moving aircraft is another matter) and away from any thunderstorms. How much do the payloads weigh? They look like they might be pretty light. Could it be something like vortex shedding as the balloon rises, becoming resonant with the pendulum period of the payloads hanging below? The vortices may hit the lower payloads in a rhythmic fashion, causing them to swing more and more.

If you watch a helium party balloon with a light string attached to it rise, you can see this happen too (not the pendulum effect so much, but the balloon swinging rhythmically).
Having the atmosphere itself be this violent on this small of a scale is pretty unusual to say the least, and to have it happen to two different flights on different days would lead me to focus back on the flight train characteristics instead of the atmosphere.

I was thinking the same thing Mark. The elasticity of the balloon while encountering even minor turbulence may induce a resonance with the payloads.

If anything, on our few flights, our payloads are extremely far apart. My reason being to reduce cross-talk and interference between the payload radios, but the by-product is an extremely low frequency of resonance, similar to a implementing a long tail on a kite. My two top payload videos showed no such action as observed in the BASE video until after burst.

However, the atmosphere is big, and there is still enough air up there to cause a rough ride for our high-altitude planes. Could be that this is a fluke phenomenon of the atmosphere in this case.

If it were me, I would try increasing the length of the tethers significantly which will greatly reduce the frequency of mechanical resonance of the string, especially important if the payloads are really light. The distance from the balloon to the parachute as well as between the payloads would all increase. 15-25 feet between each piece would be my start, depending on the number of payloads. You can also add a fair weight to the bottom end of the string, such as the infamous water bottle about 1/4 filled. The mass will help dampen the string and provide a point to follow on the way down.

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-18 23:11:13 UTC
From: BASE
Topic: 6209 Message: 6212

To Mark's question about the payload weight, I don't know the details for the November 12 flight. I know that the October 17 flight had a total payload weight of 11 pounds (just below the FAR 101 exemption).

I do have similar pods and the APRS beacon pod weighs about one pound. The camera pod with two cameras would be similar or a little more massive. There would also be a 900 MHz command pod that is somewhere around 1 and 1/2 pounds. I don't know what else flew on the last flight.

The tether line length and resonance phenomena is interesting. Typically, Taylor flies with about 10 feet between the balloon and the parachute and 8 feet intervals between all other items. For the October flight the total flight string length was about 100 feet from balloon to lowest pod.

Of course, we need to remember that Taylor has flown more than 200 times and only observed this twice. No one else has reported a similar occurrence (recalling a total of more than 500 flights). Taylor flew two balloons on October 17 (launched 10 minutes apart with similar ascent rates and payload weights) the first saw the pre-burst chaos the second didn't.

Howard

Hi Howard,

Man, that's persuasive! Before the burst, I noticed several frames where the inflated balloon appeared on or below the horizon! And I agree with Mark that we've never observed that sort of chaos during ascent - although we don't carry video on many of our flights.

All that I can think of as a mechanism is a VERY slow, near stall, ascent rate passing through a very strong upper air rotor. I've never seen the latter phenomenon documented in the literature before, but I've not researched it thoroughly, either. It's possible that these videos may be some of the only observations of such a thing.

We have observed the effects of much milder and more dispersed rotors from the GPS-derived ascent rate data, but nothing close to what might actually invert a flight string.

Do you have any idea of what the ascent rate might have been during these events?

BTW, my video viewer didn't show a progress bar, so I wasn't able to drag it or pause it. The series of stills don't show the horizon, but sure show the collision and burst.

My last flight of 2006 shows similar rocking. Here's a link, the video is
on the page.

Do you have an idea about what altitude the turbulence occurred?

To me, this collection of videos do certainly demonstrate layers of CAT exist very high up, several times higher than what I personally expected.

It appears that rotors and currents flow through the upper atmosphere at times that are quite strong, without much or any indication they might be present until you hit them, truly CAT.

So when are you guys going to put a Doppler system on your balloons so you will have a warning signal that flying in that airspace could be hazardous? :)

Doug - W5BL, has been wanting me to fly an accelerometer in our flights, and this effort was shelved due to other priorities, but correlating the the ride data to altitude would be interesting and worth while data on the odd chance we run into CAT as some of these flights have.

One thing I noticed that probably added to this instability at high
altitude was the actual instability even at release.

Even when it was only a minute or two after launch it was crazy wild un
stable. It seemed the whole flight right from release was horribly
unstable.

Joe,

Please keep in mind that the video is not continuous! Jason isolated sections with the greatest turbulence. The videos begin with about 30 seconds at launch, and the spinning is typical for most of our flights. The key in the early ascent is that the radio pod remains located below the down camera and the balloon above the up camera. The system is spinning about an axis through the payload string. However, the rest of the video comes from the minute before balloon burst. The system is approximately 70,000 feet.

Having watched a lot of our videos, the instability after release damps out and is not present throughout the flight. I am confident that if we saw the hour or so of missing video we would see stable, although slowly spinning images of the ground and the balloon.

Howard

Taylor did a flight on November 12 from Fishers, IN (see ARHAB Balloon

Schedule)
that experienced pre-burst chaos. Burst was accomplished with one of the
payloads.

Two videos and a set of still pictures have been posted on the web at:

PRE-Burst Chaos Down Video -

http://www.nearspac enetwork. com/video/ preburst- chaos-vidoeo- 111209

PRE-Burst Chaos Up Video -

http://www.nearspac enetwork. com/video/ preburst- chaos-vidoeo- 111209-1

Payloads Bursting Balloon Frame by Frame -

http://www.nearspac enetwork. com/photo/ albums/payload- burst-the- balloon

This is not from the flight of October 17 that Jeff Dailey posted a

single frame
from recently.

Does the phenomena occur more often when the mid-stratosphere jetstream

is changing?

Mike,

I don't know the ascent rate for the November flight but suspect that it was similar to the October flight at about 1200 - 1500 feet/minute.

Since my son participated in the October flight, and had accelerometer data for parts of the ascent, there were two times where the acceleration increased dramatically. These events happened when the forward velocity of the balloon suddenly (within 30 seconds) increased from a slow jog (about 5-6 miles/hour) to highway speeds (65 mph +). The second event happened at about 53,000 feet and resulted in a loss of signal from the accelerometer. The instability that burst the balloon occurred above 80,000 feet

There was no sign of a near stall in the vertical ascent data. But the winds did shift dramatically.

Joe,

I think your slow release with the line and the payload system perfectly still plus the inertia arms makes a big difference.

ahh Ok,

I just though that it was crazy even right at liftoff, none of ours
ever do that.

BASE wrote:

Joe,

Please keep in mind that the video is not continuous! Jason isolated
sections with the greatest turbulence. The videos begin with about 30
seconds at launch, and the spinning is typical for most of our
flights. The key in the early ascent is that the radio pod remains
located below the down camera and the balloon above the up camera. The
system is spinning about an axis through the payload string. However,
the rest of the video comes from the minute before balloon burst. The
system is approximately 70,000 feet.

Having watched a lot of our videos, the instability after release damps
out and is not present throughout the flight. I am confident that if
we saw the hour or so of missing video we would see stable, although
slowly spinning images of the ground and the balloon.

One thing I noticed that probably added to this
instability at high
altitude was the actual instability even at release.

Even when it was only a minute or two after launch it was crazy wild un
stable. It seemed the whole flight right from release was horribly
unstable.

mw@... wrote:

Do you have an idea about what altitude the turbulence occurred?

To me, this collection of videos do certainly demonstrate layers of
CAT exist very high up, several times higher than what I personally
expected.

It appears that rotors and currents flow through the upper atmosphere
at times that are quite strong, without much or any indication they
might be present until you hit them, truly CAT.

So when are you guys going to put a Doppler system on your balloons so
you will have a warning signal that flying in that airspace could be
hazardous? :)

Doug - W5BL, has been wanting me to fly an accelerometer in our
flights, and this effort was shelved due to other priorities, but
correlating the the ride data to altitude would be interesting and
worth while data on the odd chance we run into CAT as some of these

flights have.

Hi Howard,

Man, that's persuasive! Before the burst, I noticed several frames where
the
inflated balloon appeared on or below the horizon! And I agree with Mark
that
we've never observed that sort of chaos during ascent - although we don't
carry video on many of our flights.

All that I can think of as a mechanism is a VERY slow, near stall, ascent
rate
passing through a very strong upper air rotor. I've never seen the latter
phenomenon documented in the literature before, but I've not researched it
thoroughly, either. It's possible that these videos may be some of the
only
observations of such a thing.

We have observed the effects of much milder and more dispersed rotors from
the
GPS-derived ascent rate data, but nothing close to what might actually
invert
a flight string.

Do you have any idea of what the ascent rate might have been during these
events?

BTW,
my video viewer didn't show a progress bar, so I wasn't able to drag
it or pause it. The series of stills don't show the horizon, but sure show
the collision and burst.

Dear Mike,

I dug a little deeper and found the APRS record for the flight. The beacon was KB9ZNZ-2 (as noted on the ARHAB website). It flew again on November 13, and I had to get into aprs.fi to find the path for November 12. The ascent rate, calculated as a single average from 2400 feet to 62200 feet came out at 1700 ft/min. The last nine data points on ascent are above 2000 feet per minute. [The data shows a inverted "Hanks knee", thanks Nick:)]

Here are the ascent reports

2009-11-12 18:47:30z 16 MPH 290° alt 2480 ft
2009-11-12 18:48:30z 21 MPH 254° alt 3795 ft
2009-11-12 18:49:30z 14 MPH 239° alt 5157 ft
2009-11-12 18:50:30z 35 MPH 243° alt 6548 ft
2009-11-12 18:51:29z 15 MPH 330° alt 7994 ft
2009-11-12 18:52:29z 23 MPH 262° alt 9464 ft
2009-11-12 18:53:29z 30 MPH 205° alt 10878 ft
2009-11-12 18:54:29z 23 MPH 216° alt 12292 ft
2009-11-12 18:55:28z 37 MPH 148° alt 13736 ft
2009-11-12 18:56:28z 25 MPH 208° alt 15166 ft
2009-11-12 18:57:28z 19 MPH 176° alt 16609 ft
missing minute
2009-11-12 18:59:27z 19 MPH 118° alt 19647 ft
2009-11-12 19:00:27z 6 MPH 194° alt 21199 ft
2009-11-12 19:01:27z 19 MPH 80° alt 22764 ft
2009-11-12 19:02:26z 30 MPH 147° alt 24362 ft
2009-11-12 19:03:26z 37 MPH 175° alt 25979 ft
missing minute or perhaps next time is off
2009-11-12 19:05:13z 46 MPH 138° alt 27577 ft ??time stamp??
2009-11-12 19:05:26z 35 MPH 153° alt 29197 ft
2009-11-12 19:06:25z 62 MPH 168° alt 30900 ft
missing minute
2009-11-12 19:08:25z 70 MPH 164° alt 34263 ft
2009-11-12 19:09:25z 45 MPH 165° alt 35952 ft
missing minute
2009-11-12 19:11:24z 35 MPH 137° alt 39584 ft
2009-11-12 19:12:24z 48 MPH 151° alt 41588 ft
2009-11-12 19:13:24z 58 MPH 124° alt 43452 ft
2009-11-12 19:14:24z 50 MPH 142° alt 45345 ft
2009-11-12 19:15:23z 38 MPH 99° alt 47333 ft
2009-11-12 19:16:23z 70 MPH 124° alt 49321 ft
missing minute
2009-11-12 19:18:23z 14 MPH 156° alt 53582 ft
missing minute

2009-11-12 19:20:22z 6 MPH 89° alt 57936 ft

2009-11-12 19:21:22z 46 MPH 125° alt 60032 ft

2009-11-12 19:22:23z 27 MPH 82° alt 62158 ft

Here is another case of going from 6 mph to 46 mph in just one minute (similar to what my son observed in October).

Obviously, the more information we have, the more we can learn.

Howard

The recovery team is within 200 yards of the payloads.

Yes they did get clearance from the airport to fly.

APRS 144.39 KB9ZNZ-6

I also noticed on the schedule that the flight on 11-14-2009 that it was cancelled this is incorrect the flight did fly and the callsign was KB9ZNZ-14..

Jeff,

I put the flight of the 14th back on the page but since there is no APRS data for the flight you said it would be... kb9znz-10, how was I to know that? I've changed the flight call also and now of course if shows up.

Guys,
A lot of the announcement page is automated. This means if you don't give me good/accurate information then things may go wrong... as is demonstrated here.

Thanks....

Sorry Jeff.

Also, please note, since I don't have a launch site for the KB9ZNZ-6 flight I don't have links to either the launch site or for that matter the flight track via aprs.fi.

This flight too had the wrong call sign on it. I'm doing the best I can but I have no way to guess what call sign you are going to use unless you tell me.

What were the coords of the launch?

I've been discussing with friends the best way to max. altitude with a HAB. Some think a 3000 gram balloon with enough lift to carry a minimal payload will go highest. My gut says that's not *necessarily* the case - that a light payload carried by a physically smaller balloon will go higher as you don't have to carry the 'extra' weight of the balloon itself.

What do the experts think?

The more the balloon can expand, the higher it can go. Be aware there mst be enough positive lift to keep the balloon rising. In either case, I'd connect a cutdown to the balloon to trigger some three hours into the mission, just in case.

KC0GPB-11 flew Monday, 11/23/09 to an altitude of 100,000'. We again had antenna problems with the GPS connected HT but did recvover the payload after a long search by RDFing a separate, back-up beacon.

We got some stunning images from the onboard camera I'd like to share with this slide show:

Hi Pete,

Going higher in altitude means you must displace a larger volume of ambient air. And a big balloon will do that better than a small one, before bursting, that is. As a rule of thumb, air density drops by a factor of 10 every 50K' in altitude. So to hit 100K', the balloon volume must expand 100x from its sea level value, and 1000x to hit 150K'.

Yes, it's a conundrum, and the solution is to come up with a balloon envelope material that's lighter than fully-distended latex or 0.25 mil polyethylene. Like noweightum? :=}. Short of that, keep the total weight to a minimum, and about the only areas we in ARHAB can do that is in the payload and parachute. Like the guys from Cornell (?) did to make close to 130K' with a 3000 and a 1/4 lb payload.

The unmanned balloon altitude record was set at about 170K' in the early '60's by USAF with a huge plastic ZP, probably carrying no more than a radar reflector.

Pete and all....although some folks have gotten pretty high and set records with 1200 and 1500 gram balloons....I would also agree that a 3000 gram with a very lightweight payload is the best way to go....I have a couple spare Kaysam 3000 gram balloons left if anyone is interested.

My pinhole vent experiments would also allow you to float at peak altitudes until the UV radiation finally gets to the envelope....although I'd recommend a slow ascent rate to allow the excess pressure to vent at peak altitude. Even if it does burst at peak altitude, you'll get a bit higher with a pinhole leak in it unless the vent hole is too big and then it'll level off at a lower altitude and then come back down intact.

My last pinhole floater parked itself at 107,000 feet all night long over Tennessee (turnaround time in late April). Basically I put a PVC pipe in the balloon nozzle with a 1/16" hole in the endcap to act as a continuous vent....that works with a 1500 gram balloon...you'll have to experiment with the hole diameter for other size balloons. In flight tests, it floated successfully if the ascent rate going up was under 500 ft/min...over 500 ft/min it still went high but burst.....best to launch this kind of experiment about 2 hours before sunset. By the way, two 1/16" vent holes caused the 1500 gram balloon to level off at 28,000 feet and then come right back down at about 300 to 600 ft/min descent rate.

The UK group has reproduced this effectively recently.

I used 1" diameter electrical conduit pipe from Lowes by the way.

Hi Pete,

Going higher in altitude means you must displace a larger volume of ambient air. And a big balloon will do that better than a small one, before bursting, that is. As a rule of thumb, air density drops by a factor of 10 every 50K' in altitude. So to hit 100K', the balloon volume must expand 100x from its sea level value, and 1000x to hit 150K'.

Yes, it's a conundrum, and the solution is to come up with a balloon envelope material that's lighter than fully-distended latex or 0.25 mil polyethylene. Like noweightum? :=}. Short of that, keep the total weight to a minimum, and about the only areas we in ARHAB can do that is in the payload and parachute. Like the guys from Cornell (?) did to make close

to 130K' with a 3000 and a 1/4 lb payload.

The unmanned balloon altitude record was set at about 170K' in the early '60's by USAF with a huge plastic ZP, probably carrying no more than a radar reflector.

Great work, Pete. Nothing like a backup beacon to keep Murphy at bay!

We get some isolation between the GPS antenna and the radio by extending
the flexible 2m J-pole coax a few feet out the bottom of the payload and using
Al foil shielding between the GPS rcvr and radio inside the box.

That was silly of me to have forgotten to include that information. We flew
a Canon A570 Powershot using the CHDK script lifted from the EOSS web site.
We did experience under-exposure and over-exposure at the points in the
flight shich you can obviously guess (above and below the clouds).

Thanks, Mike.

Our antenna problem was mechanical. We used a Slim Jim J-pole with the coax connection outside the payload suspended by a zip-tied cord. That looks all fine and dandy on the ground and seems adequate. What I think happened is that the window wire antenna hanging below the box is helical and that simply screws itself tight as the balloon ascended to 100K'. The PBC must have been enough to snap the coax connection as we lost all GPS packets at apogee.

The RDF beacon did save the day to be sure. We drove about 275 miles searching and listening with no luck. We then gave up and went home when it got dark. Both my balloon partner and I then looked online at the aprs.fiinfo / map and made some mental notes about where we had 'looked' and
listened and thought we'd better check one area we didn't drive but still seemed an obvious place for it to have landed. Sure enough, after just a few minutes of driving we heard the RDF beacon and were able to foxhunt our way through a picked corn field in the cold and dark using flashlights and past experience RDFing to find the payload intact almost 12 hours after release. We did keep Murphy at bay using the old fashioned technique of attenuating the signal to the antenna-less HT using a human body and working our way toward the box. From a failed GPS signal to using a human body - this recovery used all of our radio skills.

I am embarrassed to admit it publicly but what the heck - I dunno any of you! - the helical twisting and coax break was a case of not learning from my mistakes. We had the same problem on our last flight and I simply failed to follow through on making corrections. We had moved our launch date up one day and a case of Go Fever allowed me to forget to make the change to the antenna mounting. Next time...

Hi Pete,

Hey, nice recovery, man! Plus some pretty good foxhunting by a single team, to boot!

We used to suffer from unscrewing BNCs until I started soldering wire tangs onto the male shell that hooks onto a safety line secured to the payload enclosure. It works excellently unless someone pulls the safety line loose before launch :={.

Another trick that we learned (over & over, it seems) is make SURE there's enough slack in the copper to accommodate up to 150% stretch in the woven nylon to the yield point. We strap the J-pole to the line in 2 or 3 places to keep it close to vertical in flight.

You should be embarrassed!... None of us have ever done that before. :)

At the GPSL this year, I totally lost it with our parachute implementation. This was a discovery flight to sense internal pressure characteristics of the balloon, and so our parachute was under and not over the payload. The parachute was supposed to have a rubber band and a weight to hold the chute closed through the ascent, whereas the rubber band would give in the descent due to the force and speed of the payload dropping, and the weight would help keep the parachute closed all the way up - but not effect the descent effectiveness.

Both the weight and the rubber band were still in the truck --- while we watched the parachute open seconds after liftoff... Arrggg... We had a 3+ hour ascent. To top it all off, I tied the chute too close to the payload, so when we hit burst, the payload landed in the chute and we had a 30-45 minute return from about 100,000 feet. :)

Oh yah, and I even had a check list with all those missed steps on it. I really do hate staying up until 3AM working on last minute issues with payloads... :)

While I would certainly entertain the idea of a 'guest' experiment onboard a flight I am thinking my friends and I have a lot to learn before a record attempt. We've flown just 3 HABs and all have had substantial issues despite being successful in the end.

The one of us pushing this idea tends to have more ideas than actual practice. Nothing wrong with having those guys in a group - in fact they can be beneficial. It's just that I'm not willing to risk my equipment on a mission like that without learning a whole lot more about HABing first!

Hey Pete,
Another tip would be taking really good care of the balloon you are using - make sure that it is as new as possible and has been exposed to as little light as possible, don't get it out of its sealed bag until you are ready to inflate. Also take care when handling it, its been suggested that you should wear gloves to avoid getting an oil from your skin on the balloon. For a record attempt its the little things that will get you that little bit higher!

6245. Mike's Fill Nozzle

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-27 00:12:44 UTC
From: Pete Lilja
Topic: 6245 Message: 6245

A few months ago Mike Manes described and sent some photos of his design for a balloon nozzle fill plug made from PVC plumbing pieces. I made a couple last week and used one on our most recent HAB flight. It worked beautifully for filling, sealing and attaching the 1200g balloon and also for checking adequate lift.

Here's a link to a photo of what we used:
http://s33.photobucket.com/albums/d94/bigheadpete/?action=view¤t=IMG_2217.jpg

Since our flight team consisted of only two people and four hands on the last two flight this set-up made things much, much easier for us.

Thanks for the idea, Mike. This is too good not to share.

Thanks, Pete, but the PVC nozzle idea was conceived by EOSS's Balloonmeister Emeritus, Merle McCaslin, K0YUK. I just reduced it to practice.

BTW, what's the make & model of the PVC reducer that you used? Not sure any off-the-shelf fitting would have adequate wall thickness to accommodate that groove.

I stand corrected.

I agree - the groove is massive. I bought the fitting at my local Ace Hardware store. They call is a 1" to 1/2" bushing with internal threads and a slip fit for the 1" pipe side. The coding on the back edge says 438-130 CHARLOTTE D-2466. These particular fill plugs were sized for a 1200 gram Kaymont balloon nozzle. The balloon's nozzle fits over it without too much stretch. The max OD measures 1.3165" and the turned section was reduced to .97" and gives plenty of room for a 13/64" hole for the nylon suspension line hole. A zip-tie around the nozzle in the groove holds fast.

Until looking for pieces to make these fill plugs I never knew how much design variation there is amongst so many different manufacturers of PVC plumbing parts.

Hi Pete,

Thanks! D-2466 is an ASTM spec, and 438-130 is the Spears P/N for a 1" PVC to 1/2" NPT-F fitting - same series as the one we use for 3000's, p/n 438-209, 1 1/2" PVC to 1/2" NPT-F. Nice to know that Ace carries it, and that you've already flight qualified it!

I'd think that 1/8" holes would support a double loop of 250# woven nylon line - plenty good for any load that a 1200 can haul up.

And I'd also think that the zip tie wouldn't have to tensioned to its limit to get the job done - just so long as its ID is less than the adaptor OD + 2 latex neck wall thicknesses.

Reckon I've got a trip to Ace and some work in the shop to do.

That is good to know. I didn't realize it was your recommended brand of Spears. Sometime you just get lucky, I guess. And that Ace hardware is the closest retail store to my house so I frequent it often.

I suspect you're right on the zip-tie. We just pulled it snug and clipped off the tail. It wasn't going anywhere. I'd also guess you're right about the nylon cord. What I used was from a package of cord I had on hand. A smaller diameter would be easier to install and work around.

This set-up worked so well for us I can't imagine not using them on future flights. It allows a handhold and an easy way to maintain a safety line, a place to attach to check lift, a place to attach the payload and an easy method to plug the nozzle. With us not using a cut-down device it is reusable. All around it is a simple design that makes releasing a balloon easier without much of a weight penalty.

Pete

Hi Pete,

I've looked at several other brands of PVC reducers of the same size, and none of them appeared to have thick enough walls to take an 0.05" deep groove without significant weakening. And I kinda like that conical outlet for the fill gas - looks like a rocket nozzle! See how aberrant a dumb ol' EE's thinking is when it comes to machinery :=P.

6251. [GPSL] WB8ELK Fill Nozzle

Yahoo group: GPSL (2009 — 2010)
Date: 2009-11-30 00:14:53 UTC
From: wb8elk@aol.com
Topic: 6245 Message: 6251

Thought I'd show how I build a filling nozzle.

http://www.wb8elk.com/launch.htm

The main filling nozzle part is a 1" Quick-Fix Repair Coupling from either Lowes or Home Depot in their PVC pipe area.

The Repair Coupling part has a 1" PVC pipe that slides in and out of a larger piece to allow you to hook up two PVC pipes with an adjustable distance. It's a part that just seems to made for use as a balloon filler.

I glue in a 3/4" to 1/2" threaded plastic reducer adapter. Then put a 3/4" to 1/2" M-F brass adapter following by an NPT pressure fitting (either male or female depending on what you have on the end of your filling pressure hose). Make sure to use nylon tape on the threaded fittings to seal them.

The top nozzle assembly is the one from Home Depot...the bottom one is from Lowes. Either one will work but the one from Lowes has an indented area near the end that will help hold the balloon on. These are pretty thick so you can also file, Dremel or lathe a groove in it as well.

I tie on a string over the lip of the bottom part of the nozzle filling adapter to hold the balloon down and to measure the lift...it works pretty well.....The NPT fittings allow you to quick release the nozzle from the hose (make sure to close the helium tank valve first) to allow you to accurately measure lift without the helium dumping out...provided you use the female NPT fitting on the nozzle. I also have these fittings on both ends of the fill hose as well as the pressure regulator which allows me to quickly disassemble and pack away the filling system.

Just remember to use a pressure regulator on the tank...the pressure hose from Lowes or Home Depot is only rated to about 300 PSI.

If you want to bypass the use of a regulator, then make sure you have male NPT fittings on each end of the filling hose....but I still recommend using a regulator.

One nice feature when packing things away is that the business end of the nozzle filler is adjustable and can be pushed into the adaptor housing to make it very compact for storage. Just pull it out again for filling...it has a rubber seal inside.

Subject: [GPSL] Mike's Fill Nozzle

A few months ago Mike Manes described and sent some photos of his design for a balloon nozzle fill plug made from PVC plumbing pieces. I made a couple last week and used one on our most recent HAB flight. It worked beautifully for filling, sealing and attaching the 1200g balloon and also for checking adequate lift.

Here's a link to a photo of what we used:
http://s33.photobucket.com/albums/d94/bigheadpete/?action=view?t=IMG_2217.jpg

Since our flight team consisted of only two people and four hands on the last two flight this set-up made things much, much easier for us.

Thanks for the idea, Mike. This is too good not to share.

Very nice. I picked up one of those repair couplers the other day and looked it over for similar use. I hadn't thought through as completely what you've done. It does seem like another good idea. Thanks for sharing. I enjoy seeing how others solve these HABing problems.

6254. Flight Announcements

Yahoo group: GPSL (2009 — 2010)
Date: 2009-12-01 18:47:15 UTC
From: Keith Kaiser
Topic: 6254 Message: 6254

I have created a stand alone form to submit flight announcements. Located at; http://www.arhab.org/annomail.html this page uses a third party site to send me an eMail formatted to make building the announcement page easier.

I've sent about a dozen experimental announcements using this page and they all work. From Windows running IE 6, and 7, using Safari, and FireFox, under Windows 7 using all the same, and it works every time. I've sent it from Ubuntu and SuSe, Mac OS 10.5, and 10.6, I've yet to break the new form.

So please use this form for submitting your announcements, I would really appreciate it.

Thanks.....

6255. USWS HABs

Yahoo group: GPSL (2009 — 2010)

I was getting a haircut earlier today with Jeopardy on the barber shop TV. My attention was piqued when I heard a video 'answer' posed dealing with balloons and the US Weather Service. I didn't hear the 'answer' as the guy in the chair next to me started talking loudly at the same time but it must have been lame as the correct response was reduced "air pressure."

Even more interesting was the little info. blurb right before the commercial break that said 20% of the 750,000 radiosondes launched under balloons by the USWS each year are returned by people that find them thus saving the taxpayers' money. It also mentioned the 2 launches / day by WX stations all over the country I've heard before.

WoW! That's a huge number!

I think there's an extra zero in the figure for the number of radiosondes.
About 100 stations fly sondes in the US, so 100*2*365 is 73,000 per year.

I remember hearing a 20-25% return rate even 20 and 30 years ago. I tried
to Google for an up-to-date answer and the only thing I found were quotes of
"less than 20%" and "extremely low".

That sounds much better, Mark. I am sure, however, that Jeopardy said 750K as I was astounded and I don't know how many weather stations there are around the country. But an understandable error. And still a big number!

Hi Pete,

I'd heard that the return rate for RAOBs in CONUS is more like 75-80%. I'll check that with EOSS's NOAA members.

And yeah, the more interesting statistic is the absence of ANY reports of mid-air collisions between aircraft and RAOBs, and only a few non-injury collisions with surface vehicles. Pretty good indication of the sort of risk that ARHAB flights assume, especially when our flights I-gate APRS data in real time to FAA control floors.

From: wb8elk@aol.com
Topic: 6260 Message: 6260

If you see any of the DARPA challenge balloons....tethered red balloons with a white banner and number below it....please forward the lat/lon coordinates to me or the list ... I've entered on behalf of GPSL so lets see if we can get all 10 !!! If we somehow manage to win the prize, I recommend half of it be used for upcoming GPSL conferences with the other portion split between those who first make a sighting of one of the balloon.

Is anyone seeing anything? I'm ready and willing to mobilize, but I'm not seeing anything out here.

BTW, according to the meta-data on the JPG of #10 balloon (https://networkchallenge.darpa.mil/default.aspx), it looks like it's in the eastern time zone. Crossing the clear-blue skies against the current weather map, I'd guess that it's in the TN/LA/MS area.

Not quite within the 1 mi radius I'm afraid.

Subject: [GPSL] Balloon Challenge

Is anyone seeing anything? I'm ready and willing to mobilize, but I'm not seeing anything out here.

BTW, according to the meta-data on the JPG of #10 balloon (https://networkchallenge.darpa.mil/default.aspx), it looks like it's in the eastern time zone. Crossing the clear-blue skies against the current weather map, I'd guess that it's in the TN/LA/MS area.

Not quite within the 1 mi radius I'm afraid.

KB9ZNZ-11 is in the air just south of the Salton Sea in CA. at 75,000'.

Nothing spotted around Grand Island, NE, but then I'm not surprised. If one were to end up in Nebraska I would expect it to be in Omaha or around the Strategic Air Museum.

We have 100 percent confirmation of Balloon 3 which I confirmed in a very unusual way:

I received an email but no photo from a fellow in Charlottesville VA who said he had found Balloon 3 and sent me the coordinates. The Google Map showed it in the middle of a tennis court.

Then I found out people were selling positions on eBay....and sure enough there was Balloon 3's position for sale in Charlottesville VA by another fellow who was trying to get $500 out of it....he even included a photo which showed the balloon right in the middle of a tennis court !!!!

http://cgi.ebay.com/DARPA-Red-Balloon-3-Location_W0QQitemZ200414562396QQcmdZViewItemQQptZUS_Nonfiction_Book?hash=item2ea9a3885c

And the $9000 bid:

http://cgi.ebay.com/DARPA-Red-Balloon-Locations-2-3-5-7-8-9_W0QQitemZ110466464994QQcmdZViewItemQQptZLH_DefaultDomain_0?hash=item19b8507ce2

Here's a link showing all the open Balloon groups...they are also using Twitter and Facebook.

http://redballoon.wikispaces.com/Groups

I also have a report of Balloon 5 that was emailed to me from a park in Memphis, TN that sounds believable...but couldn't find anyone to drive out there in time to confirm it.

==========
Here's my emailed report for Balloon 5:

Balloon #5
Latitude 35 degrees 08 minutes 15 seconds north
Langitude 090 degrees 03 minutes 43 seconds west
The balloon is located in Tom Lee Park on Riverside Drive in Memphis, TN right next to the Mississippi River. There were two DARPA representatives there that gave me a piece of paper with the official coordinates. Sorry no photo but I promise it is there.
Thanks,
Samuel Riney

And for Balloon 3 in Charlottesville VA:

North Lat:
38.01.33
West Long:
078.29.23

No photo's unfortunately. Camera decided to spaz out on me today. Good luck guys!

6275. DARPA balloon challenge has been won by the MIT group - Balloonatics found 4 balloons

Yahoo group: GPSL (2009 — 2010)
Date: 2009-12-06 04:10:34 UTC
From: wb8elk@aol.com
Topic: 6275 Message: 6275

Not sure if the eBay auctions are still up there...but it was fun to see all modes of social interaction being used for this challenge.... websites, Yahoogroups, Twitter, Facebook, APRS and good ole cell phones...one group even had an iPhone app to report the balloon positions....the MIT group won about 9 hours after the Challenge started.....We had 2 positive reports sent to us in Charlottesville VA and Memphis TN (at the end of this email) and had two good guesses based on probabilities of looking at all the online reports to try to figure out which were bogus and which were possibly good. I reasoned that most would be in city parks and eliminated those that seemed way out in the boonies or weren't near city parks....Zack Clobes did a percentage analysis to narrow things down, so we managed to get the Miami, FL one that way and I made a guess at downtown Atlanta GA which got us 4 total balloon positions for the Balloonatics team.

Thanks to all who helped out today...it was fun. Also thanks to Mark Caviezel for burning through gallons of fuel to confirm that none were in the DC area.

- Bill Brown WB8ELK

None were even remotely close to me, but one thing is that I am amazed
on how fast they were all located.

Now a question, is did they have a guard at each one or something? How
secure were they ya know to keep anyone from playoing with them or even
cutting one free?
What were they made of, it appears like a chloth made material?
and what diameter were they? they diddn't seem too big, which makes ya
wonder again what it was made of, because if they were indeed a fabric
type of material it had to be awful light, since if the balloon is
somewhat small it cant make a lot of lift,,

Possible superpressure type of material?

From: Pete Lilja
Topic: 6275 Message: 6278

Idle-TymeThe web site says the balloons were / are 8' diameter and there were DARPA reps. stationed at each balloon with information and coord location handouts.

I am curious as to how the locations were determined? Why were those cities were selected? It may be nothing more than that's where those DARPA people planned to be yesterday or was something else going on? Obviously huge parts of the country are left out with only 10 balloons and equally obvious is the idea that it doesn't matter where they located as information can easily get anywhere.

This whole event is pretty cool, IMO, and it'll be interesting to see the different strategies used and how these strategies are used in the future for quick information gathering. And that brings up another question: What uses can this exercise be expanded to? I see the possibility of:

1. Terror threats / activities over a large geo. area.
2. Natural disaster info gathering
3. Civil unrest activity throughout the world

What else? There could be hundreds of uses I can't think of...

Not sure if the eBay auctions are still up there...but it was fun to see all modes of social interaction being used for this challenge.... websites, Yahoogroups, Twitter, Facebook, APRS and good ole cell phones...one group even had an iPhone app to report the balloon positions....the MIT group won about 9 hours after the Challenge started.....We had 2 positive reports sent to us in Charlottesville VA and Memphis TN (at the end of this email) and had two good guesses based on probabilities of looking at all the online reports to try to figure out which were bogus and which were possibly good. I reasoned that most would be in city parks and eliminated those that seemed way out in the boonies or weren't near city parks....Zack Clobes did a percentage analysis to narrow things down, so we managed to get the Miami, FL one that way and I made a guess at downtown Atlanta GA which got us 4 total balloon positions for the Balloonatics team.

Thanks to all who helped out today...it was fun. Also thanks to Mark Caviezel for burning through gallons of fuel to confirm that none were in the DC area.

- Bill Brown WB8ELK

Actual map of where the 10 balloons were located:
https://networkchallenge.darpa.mil/default.aspx

We had 100 percent confirmation of Balloon 3 which I confirmed in a very unusual way:

I received an email but no photo from a fellow in Charlottesville VA who said he had found Balloon 3 and sent me the coordinates. The Google Map showed it in the middle of a tennis court.

Then I found out people were selling positions on eBay....and sure enough there was Balloon 3's position for sale in Charlottesville VA by another fellow who was trying to get $500 out of it....he even included a photo which showed the balloon right in the middle of a tennis court !!!!

http://cgi.ebay.com/DARPA-Red-Balloon-3-Location_W0QQitemZ200414562396QQcmdZViewItemQQptZUS_Nonfiction_Book?hash=item2ea9a3885c

And the $9000 bid:

http://cgi.ebay.com/DARPA-Red-Balloon-Locations-2-3-5-7-8-9_W0QQitemZ110466464994QQcmdZViewItemQQptZLH_DefaultDomain_0?hash=item19b8507ce2

Here's a link showing all the open Balloon groups...they are also using Twitter and Facebook.

http://redballoon.wikispaces.com/Groups

Here's our two actual sighting reports received by the Balloonatics team: Thanks to Samuel Riney and Kyle Sherill for their reports!!!

==========
Here's the emailed report for Balloon 5:

Balloon #5
Latitude 35 degrees 08 minutes 15 seconds north
Langitude 090 degrees 03 minutes 43 seconds west
The balloon is located in Tom Lee Park on Riverside Drive in Memphis, TN right next to the

Mississippi River. There were two DARPA representatives there that gave me a piece of paper with the official coordinates. Sorry no photo but I promise it is there.
Thanks,
Samuel Riney

And for Balloon 3 in Charlottesville VA:

North Lat:
38.01.33
West Long:
078.29.23

No photo's unfortunately. Camera decided to spaz out on me today. Good luck guys!
Kyle Sherrill

From: Zack Clobes
Topic: 6275 Message: 6279

They were supposedly about 5' in diameter, but the photos do look kind of odd - not like any latex I've seen.

They had a representative at the balloon. The Rep was actually handing out pieces of paper with the Lat/Lon coordinates on it as I understand.

I realize taking the lat/lon difficulty out of the loop makes it possible for anyone to participate, but it seems a bit like cheating...

Zack

Hey, thanks for that link, and, no, that's the first I'd seen of that piece.

For Bill: Great piece of reporting, including the plug for GPSL!

I'm eagerly awaiting a report on how the MIT managed that coupe in just 9 hours. Guessing they recruited a mass of mobile eyeballs from the MIT alumni association.

Winter has decided to come out of the closet here - it's been snowing off & on for 3 days now, and the temp at my place is -15C - brrrr! That could even keep Bill off the slopes!

6284. Last weeks flights

Yahoo group: GPSL (2009 — 2010)
Date: 2009-12-07 20:01:00 UTC
From: Jeff Dailey
Topic: 6284 Message: 6284

The last message was not complete driving and cellphone email does not go together well.

Friday 12-4-2009 KB9ZNZ-9 flight from the Indianapolis IN. area.
Friday 12-4-2009 KB9ZNZ-14 flight from the Elmwood WV.. area.
Saturday 12-5-2009 KB9ZNZ-11 flight from the Hovley CA. area.

We may have two or three more flights before the end of the year, as of today Taylor University is at 218 fights completed.
We will be transitioning from the HARP Command system to the HawkEye platform in January of 2010 with the first flights for the J Term class.
HawkEye will be the primary research platform.

Quick look at HawkEye:
Analog channels: 25 to 250
High speed user data bus interface
Three axis GPS configuration
Dual high speed Uplink / Downlink RF module (Secured Constellation MESH Network)
Satellite comm. link (for out of ground station network range)
Controlled Ascent / Descent rates
Altitude Hold (+- 500m)
Stabilized targeting platform (+-3 Degree)
DropSonde system

It been a great year of ballooning, happy holidays to all.

Mike,

Here's the link to the article that appeared in the online NY Times today about the DARPA event:

http://www.nytimes.com/2009/12/07/technology/internet/07contest.html?ref=technology

The article quotes an organizer and appears to be legitimate. They offered to split the money with the finders and give their half to charity.

Howard

I was just listening to NPR's Science Friday with Ira Flatow and he had a short segment on DARPA's Red Balloon Challenge with a member of the winning MIT team, Riley Crane. The segment was rather short yet Mr. Crane answered some questions as to how they did it and kept some of the things to himself for future scholarly publication.

Look at the web site: http://www.sciencefriday.com/program/archives/200912114 Nothing is posted yet but they often will podcast these programs after broadcast. Definitely worth your time to listen (or read if they post a transcript).

Maybe a tad off-topic, but something of interest to someone...

Caught a commercial (posted on Collegehumor) for an HDTV and it was interesting (for me at least) to watch:
http://www.collegehumor.com/video:1926134

An armchair sent aloft to near-space.

I was fascinated with the rigging for the camera angles used during the flight.

SPOILER ALERT: The chair breaks apart after burst...

I'd be curious to know where it was launched (looks like NM maybe?) and if anyone could decipher the packets used in the commercial.

From: k6rpt
Topic: 6295 Message: 6295

I did my first launch on 09-12-2009 and after the balloon burst, It was descending at 7☐10 thousand fpm until it reached about 25 thousand feet and then it slowed down to 1000 fpm. Is that normal?

Sounds like a fouled chute that suddenly opened, but hard to say for sure
without a list of altitude/time reports.

I have a file, beegps.kml that works with Google Earth of the flight. Would that help? I put an 8" ring at the very bottom of the parachute and I think it should be up closer to the parachute to prevent twisting? I think the line between the balloon and the parachute could have been longer, it was 15'. There was 23 ounces of latex balloon pulling the top of the parachute after it burst, I'm sure that didn't help. One of the pictures you can see pieces of the balloon after it burst; the picture is on the web site, http://www.californianearspaceproject.com/ at the bottom of the first page.

Yup. During ascent, the expanding balloon drag area compensates for the declining air density, but during descent, you just have a fixed parachute area. Air density varies 100:1 from sea level to 100K'.

Well, it's enough to float your balloon with payload, so the answer's
yes. It does help to use a spreader ring on the shroud lines to keep
the skirt a bit open so it'll catch the air ASAP after burst, however.
Note that at that altitude, your decent rate will be about 10x higher
than at sea level, however.

Ours usually open within a few seconds.

The key is does it do anything?

Nope not really, it falls like a rock for quite a while.

all depends on the weight of the payload, and the type and size of the
chute. and 1000 ftm is pretty slow even at sea level.

That all depends on the size of the 'chute and the load that it's carrying. EOSS's descent rates just prior to landing are more like 1500 - 2500 fpm at our typical mile-high landing sites.

I have a circular slide rule from U Wyo that runs those calculations. The trajectory prediction programs based on Bill Brown's work characterize descent profiles based on the user-input sea-level descent rate, which is subject to the two variables noted above.

Now, you probably shouldn't fret the landing decent rate too much. If there's a brisk breeze at the landing site, parachute drag across the ground can do a lot more damage than the initial landing impact. If your payload will tolerate being kicked down a flight of concrete stairs, it's probably strong enough.

The 'chute does open. Check my video report on this mission,
http://nearsys.com/arhab/flightdata/2006/g/index.htm

What ever is the landing speed of your payload, it will fall twice as fast
every 36,000 foot increase in altitude.

Ron,

Check out two recent videos I did of the balloon at burst using a Flip Ultra camcorder...you can clearly see the chute opening almost immediately after burst.

http://www.youtube.com/watch?v=YsQb-oWq6d4

This one shows a smoke ring of talcum powder left over from inside the balloon at burst:

http://www.youtube.com/watch?v=iHFPIdShNjU

Also...this is a complete video of the entire flight of our UAH Balloonsat launches this Fall using a Flip pointing at the horizon:

6310. Is it best for the balloon fragments to drop below the first payload?

Yahoo group: GPSL (2009 — 2010)
Date: 2009-12-20 19:51:40 UTC
From: k6rpt
Topic: 6310 Message: 6310

Thank you for all the input, I understand the decent characteristics now. I was not concerned with how hard the landing was, I just wanted to understand the decent and when the parachute should open. I watched the videos and after seeing the balloon bursting and then trailing above the opened parachute, I assume this is because of the fast decent at high altitude and as the decent slows the balloon fragments would drop below the parachute. If I'm correct is it best for the balloon fragments to drop below the first payload?

Thank you, Ron K6RPT

That's right about the fast descent. I cut my load line around 18 feet
long. I want the balloon to drop over the parachute, rather on top of it.

Hi Ron,

Actually, it's best to get rid of the balloon shards ASAP after
burst to keep them from fouling and/or destabilizing the parachute.
That's what the EOSS fast release device does rather effectively.

I say "rather" effectively, because even with that device working
properly, we've brought back a few grams of stringy shards on the shroud
lines. I believe this is because the burst event is pretty explosive,
and the neck of the balloon and any attached shards may pass below
the parachute even though the lift line is already separated. Relaxation
of tension in the stretchy nylon lift line may also play a role in
accelerating the neck downward before the tension-sensing release acts.

Efforts to get the design of that device into CAD format have been
unsuccessful so far, but the concept is simple and easily duplicated from
what's on the EOSS web site.

Hi Bill,
That burst video really shows how badly a big mess of shards can
destabilize the parachute during initial descent.

Hi Ron,

The anaeroid cell keeps the locking arm engaged until we're above 70 - 75K',
where there's little turbulence. It also keeps the jaws locked thru the
launch. THe only time it's failed was when a launch was attempted with
15 ft of slack in the lift line - the rapid lateral acceleration when the
balloon took up the slack acted on the then-unbalanced locking arm, causing
it to open and let the balloon fly free, unburdened by the payload string :={.
I've since statically balanced the arm and put in a stiffer retention spring
between the arm and the anaeroid and discouraged that launch technique.

So the answer's no.

Awr, shux, Ron. 'Twern't "engineered" - more like kludged up from a
vague idea. I mean, wotcha expect from an EE set loose in a machine shop?
Plus a healthy dose of Pure-D Warranteed dumb luck.

In that light, I'd encourage you to sneak into your neighborhood machine
shop under cover of darkness and come up with your own design - kinda
like Joe WB9SBD did.

A prang is a crash of an airship of some (any) type.

wow I have never ever heard that word before. My spellckeck even
flagged it as a non word and had no suggestions for replacement. I went
to an online dictionary ane they gave,,

prang

?verb (used with object) British Slang.
1. to collide with; bump into.

2. to destroy or severely damage by a bombing raid; bomb (an enemy
target).

3. to destroy or shoot down (an enemy aircraft).

Interesting,

I slid off the road and pranged into a tree.

Hmm, I guess any type of crash.

It's a common term used amongst high power rocket fliers after a, ah, mishap.

KWU in Salina KS, EM18, is building a payload with ATV. Wondering what frequency will be the best for this area? Got an inquiry into the KC atv group and looking to see if a group is active in Wichita with the intent not to interfere with a atv repeater they might have. Looks like the simplex atv freq is 427.250 according to the ARRL band plan. What has been done in the past? Know of any active groups that might be affected by our flight?

tnx, Pete NØOY

Hi Pete,

EOSS runs its NTSC DSB-AM ATV on 426.25. The other common freq, 439.25, has sidebands that get into the repeater input freq sub-band. We didn't get any gripes when we flew it out of Lawrence or Hutchinson at the GPSLs.

I want to say that the 427.250 was used to get away from satellite operations. I would think that if you did run a watt or two you probably would not bother anyone else unless you were close in and close frequency.

BTW: Launch one again my way Pete, we now have an APRS node here that works pretty well in the area.

Subject: [GPSL] atv freq(s)

KWU in Salina KS, EM18, is building a payload with ATV. Wondering what frequency will be the best for this area? Got an inquiry into the KC atv group and looking to see if a group is active in Wichita with the intent not to interfere with a atv repeater they might have. Looks like the simplex atv freq is 427.250 according to the ARRL band plan. What has been done in the past? Know of any active groups that might be affected by our flight?

tnx, Pete NØOY

Hi Pete an group.
The ATV National Simplex frequency is 439.250 MHZ. Most ATV'ers watch that frequency and listen to 144.340 MHZ FM for simplex contacts.The ATV'ers will use horizontal antennas for dx. My first balloon package that I sent up years ago was seen 400 miles at 100,000 feet. That is if you have a little power (i used 4 to 5 watts) and a horizontal antenna with a little gain like the ones w6oal sells. Vertical antennas a lot of times don't have the band with that is needed when sending wide band video with audio. As far as the ATV repeater here in Kansas City Kansas I have it down right now but will be back up within weeks. It uses 439.250 input and that is on a vertical antenna and if you got a signal into it that would be great so don't worry about us. The ATV repeater in Topeka Kansas is 1.2 gig FM input and 427.250 am output but is still not on the air at this time. There is just a small number of ATV'ers west and south of KC but the most are east of St
Louis. Have a great flight and let me know what date and I will look forward to looking for it. 73's Mike KDØFW Kansas City Mo.

A coworker recently gave me a meteorological balloon pictured in this link: http://i33.photobucket.com/albums/d94/bigheadpete/IMG_0818.jpg Its folded size fits just behind the description paper shown.

Am I correct in thinking it's was made in 6/87 and is a 160 gm in size?

I'm not sure what I'll do with it but I'm sure some idea will come up.

Thanks!
Pete

6/87 is the likely manufacturing date. The ML-160A is a 100g pilot balloon.

Hi Pete,
My guess is that its mfr date is 02/91. You could get an idea of its size in grams by weighing it; don't pull it from the package unless you're planning on flying it shortly - or repackage it in a ziplock bag and keep it in the dark to prevent deterioration. The packaging shouldn't add any more than 10 gm to the weight. Now, most balloons have commercial shelf life of less than 5 years with proper storage - but you may get lucky.

6335. ATV Frequencies

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-03 00:05:20 UTC
From: wb8elk@aol.com
Topic: 6335 Message: 6335

hi Pete,

In your area, you can use any of the common ATV frequencies....439.25 MHz would be received by more folks in the midwest who are on ATV as that is their usual contact frequency. However, check to see if there is any interference by local 440 FM repeaters that are near the passband. 434 MHz is a little clearer frequency but if you are in town, you'll see some interference by wireless thermometers that operate on 433.92 MHz....a common gift for Christmas...the interference starts to decrease a few months later when the batteries fail. 427.25 or 426.25 are usually fairly clear frequencies and good to use as well....we've done a number of flights on both of those frequencies with little interference....but for those near the Canadian border (Line A) you can't use those two...but that shouldn't affect you in Kansas.

I'd recommend setting up a test where you put the balloon ATV transmitter on a campus roof and trying to receive it from a few miles away. Do the test on each of the above frequencies and choose the one with the least interference.

Thanks fo all the replies. I think I have a better understanding of what
I've got now.

I believe Mike's date idea is "more" correct. That jibes better with dates
that I know when this may have been acquired.

http://eclipse.gsfc.nasa.gov/SEplot/SEplot2001/SE2012May20A.GIF

This eclipse occurs near sunset on Sunday, May 20, 2012 in the western US. The maximum eclipse occurs on a path from northwest California southeast towards central New Mexico. The ANSR group would see about 90% coverage from their usual sites. From Nebraska we would have about 75% coverage right at sunset.

If we planned for burst at sunset, it wouldn't be terribly dark at the landing for the recovery. Worst-case we'd have to get it the next morning.

I don't know if the photos would be terribly interesting, but they might be kind of unique. I don't know if we'd have enough altitude to see the gradation in the sunlight from the lunar shadow. You can see the shadow on weather satellite imagery in geo orbit.

Hi Mark,

We (myself, WA6SVT and KC6CCC) launched a balloon in the early 90's from San Clemente, California to view the annular eclipse....we did this as a spur of the moment event with three of us getting together the night before the eclipse, putting a pile of balloon electronics on the floor and building the payload and pointing mechanism....In the wee hours and suffering from lack of sleep, we used light sensors separated by a barrier connected a servo that controlled a fin in order to point the cameras at the Sun. It worked great...but in a total eclipse, you'll have to use a gyro/accelerometer solution since their won't be any sunlight to make the servo/light sensor work.

A group in Germany in 1999 flew a balloon that looked at the Earth below and studied the shadow...that worked well as well. I was about 100 miles from them and got rained out...and they did too, but at least their balloon could see the shadow above the clouds and rain.

Yes, at least if nothing else, you won't be called on clouds. I just sent
an article to N&V on a sun sensor. I'll have to see if this can be expanded
in capability.

I have been working on a high altitude space imaging platform for some time now. The plan is to use it for celestial imaging. While I am still a little away from a launch, the first mission will be solar imaging with a small Celestron C70 spotting scope, type 2+ filter, and a Nikon 9M Coolpix.

I am planning to use 3 light sensors to triangulate, Two 3 axis's digital compasses for positioning, and a gyroscope to measure angular acceleration to adjust the servo speed accordingly to maintain a relative fix on the sun.

After doing some quick research I would think that even in a total solar eclipse the sensitivity of the light sensors would be enough to maintain a relative fix on the sun.

Hi Mark.

The penumbra would be very hard to detect. even from orbit you really
can not see it. Only the totality shadow can usually be seen.

Just like during an eclipse on the ground, the ground really doesn't
darken until like the last few percent is covered at all.

Hey Bill I remember you flying at sunset during an eclipse in
California a while ago. But forgot if you got anything.

The simplest solution is the Dallas/Maxim Thermochron. They are roughly the size and weight of a stack of four dimes. If you Google "dallas thermochron" you'll find plenty of links.

Ordering one may be a challenge. Dallas/Maxim always seems to be out of stock, and people have reported that their 13-26 week lead times are optimistic. I've ordered from these guys before with good success: http://www.embeddeddatasystems.com/

You'll need a hardware reader in addition to the individual thermochrons. The software is free and can be downloaded from Maxim. Thermochrons start at about $22 each, the reader is under $30.

Hi Ron

What APRS tracker do you use? All of the Opentrackers and the TinyTrak 4 have LM335 temperature sensors. I added a second LM335 external sensor to my Opentraker 1. If you didn't care about internal temperature, it's quit easy to remote the existing sensor in either tracker. Neither will log the data but they'll both allow you to transmit the readings. If you already use some type of analog logger like a Logomatic, it would be quite easy to read an LM335 and later calculate the temperature values. I don't know enough about the one-wire sensors to comment on how to use them.

Ron,

I found this all-in-one usb temperature data logger
http://www.microdaq.com/fourier/microlite_usb_logger.php

If you are into PIC programming then the Dallas 1-wire temperature probes would be a good choice. Sparkfun, Mouser, Parallax carry a variety of them depending on your programming skills.

I have also had good delivery from embedded data systems. We have ordered over 100 of them to use in refrigerated vending machines (pop & food). I had gotten a couple from Dallas years ago and decided that they would work in the vending business. I have about 6 of them that I use for my personal use.

The only down side is that they only go down to -40 F or -40 C. Which is not quite low enough to capture the entire flight. But they provide lots of interesting data and are very easy to use.

The APRS trackers I'm using do not have any temperature capabilities, so I'm looking for good temperature data Logger to log the coldest external temperature. I like the Dallas/Maxim Thermochron that Mark listed, I will use it for internal temperature, but for external temperature I think I would need something that goes lower. What is the lowest temperature that has been recorded during a flight? The all-in-one usb temperature data logger that Earl listed goes down to -50c is that low enough?

If you want a complete temp profile, you'll need something that goes to
about -70C. Tough to find, though.

Hi Ron

We routinely see temperatures near -60C. Our LM335Z sensors are rated to -55C but will work at lower temperatures with reduced accuracy. I don't recall seeing anything rated below -55C. An all-in-one logger may be capable of sensing below -50 but the rest of the electronics may freeze below that.

Good luck

Bruce

You could use a Hobo datalogger and thermistor. I wrote an article on that for the Society of Amateur Scientists and it's still online (www.sas.org/tcs).

<shameless commericalism>
You could also purchase a BalloonSat Mini and Temperature Array kits from my website (nearsys.com/catalog)
</shameless commericalism>

Nice job on the BalloonSat boards Paul; I will keep all of them in mind for my projects. My only concern is the -55C rating on the LM335 sensor. I found a Dry Ice Data Recorder w/ External Input at http://www.microdaq.com/logtag/dry-ice-data-logger.php the price adds up when you buy the logger, sensor and software. Measurement Range with (External Sensor) is -80°C to 40°C.

As it was mentioned earlier, the LM335 still works below -55. My record of flights has spreadsheets of weather data recorded during missions. The weather station uses the LM335 and recorded temperature readings to below -60. The data is smooth, so I suspect there's no abrupt errors introduced.

This temperature sensor data logger discussion raises some interesting fundamental issues. The -55 deg Celsius limit is simply the lower limit of the testing conducted by National Semiconductor on the LM335. Looking at their data sheet, the calibrated error on the device appears to be fairly linear on the low temperature end. This is consistent with Paul's data.

However, we must always remember that normal specification sheets do not consider the unique environment that is found by high altitude balloons. As is noted on their datasheet: Note 1: Accuracy measurements are made in a well-stirred oil bath. For other conditions, self heating must be considered.

Additionally, the performance may be affected by the reduced air pressure.

We have had some success with using simple diodes as temperature sensors. There is the opportunity for someone to fly multiple sensors together on multiple flights to confirm the performance of each type.

In the NTBP it was found the DS1820 also will go well beyond it's spec
(-89F measured and reported) and be fairly accurate based on other
references known at the time of the flights. Of course this device is
digital so it will not interface directly to most data loggers, but
can be used easily with a Parallax Stamp or other embedded system.

To aid with better temperature measurement where self-heating is
likely (thin air providing less heat conductivity) use of a heat-sink
is very beneficial. The heat-sink will alleviate some of the self
heating of the sensor if the surface area of the sensor is more
affected by a predominent ambient environment. To conduct heat away
from the sensor and provide more ambient air effect on the sensor, I
install the sensor in a brass tube of a few inches of length and epoxy
it in place, making sure the body of the sensor is adequately
contacting the tube with heat-conductive grease and complimentary
diameters of the TO-92 device.

Another issue is sun exposure. I keep my sensor inside a white tube to reflect sunlight away, but to let air flow (what little air there is).

6356. Re: [GPSL] Re: Temperature sensor data Logger

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-06 22:59:53 UTC
From: Mike Manes
Topic: 6342 Message: 6356

The largest source of error with the LM335-class of temp sensors is
self-heating from the power dissipated from the bias current, especially
at high altitude where convective heat transfer is very weak. This can
be minimized by shutting off the bias current except during the measurement
interval, but that's not commonly available using ordinary beacon generators.
It also helps to bond the package to a well ventilated heat sink exposed to
the outside air flow. Self-heating errors show up clearly as differences in
temp measurements at specific altitudes between the slow ascent and fast
descent. This anomoly can be a handy way to confirm burst, however - just
look for a very abrupt drop on outside air temp telemetry :=}.

Another error source is solar heating which can be minimized using a aun
shade or painting it with an IR-reflective paint (beats me where on can
find it, though).

If one really wants precision air temp measurements, then consider a Platinum
RTD from Omega or such, and keep the bias off except during resistance
measurements. Or use a thermocouple with an ice point and signal conditioner.
The solar heating issue would still remain, however.

The LM335 also shows that the internal temperature of the near spacecraft drops at balloon burst, but that it takes a little time for the cooling to be seen inside the Styrofoam airframe.

6358. GPSL 2010 lodging

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-16 00:04:14 UTC
From: BASE
Topic: 6358 Message: 6358

Dear all,

Does anyone have a recommendation for lodging for GPSL 2010 in Hutchinson?

I look forward to seeing you all again.

Howard

I'd recommend AGAINST the Holiday Inn. Worst room I've ever had - even
worse than Motel 6's.

I suppose I need to get some information updated on the website...

We will be meeting at the Cosmosphere, and there aren't any hotels in the immediate vicinity. The Days Inn got good reviews on Google, and is fairly close. The Holiday Inn and Grand Prairie are also in the same basic spot. The Grand Prarie has a neat in-door swimming pool that would be good for kids, but the people that have stayed there have given it less-than rave reviews (noise, older-style rooms, expensive, etc).

The Hampton Inn Hutchinson also got good reviews, and I believe is the newest hotel in town. Note, Google Maps shows it on Main Street, but it's actually at 11th and K-61, right next to an Office Max.

Sorry I can't be more specific - I just live here. I don't use the hotels.. ;-)

Zack

PS Mike, wasn't it the Grand Prairie that you disliked so much?

As I recall, we stayed at the Comfort Inn on 17th Ave in 2004 and the hotel was fine. Can't believe it's been almost six years since I went to that GPSL (I missed 2006 due to a funeral).

This is the 10th GPSL. Should we celebrate?

Who would have thought that having Weatherwise magazine ask about covering a near space launch would have lead to this?

Patio gas and LPG are a mix of butane and propane. Titan's atmosphere
has a little methane and other light hydrocarbons.

Some more details at http://en.wikipedia.org/wiki/Titan_Saturn_System_Mission

6365. Video capture solutions

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-19 03:25:31 UTC
From: Mark Conner
Topic: 6365 Message: 6365

Video gurus,

I'm in the process of digitizing everything I have on tape, including a couple dozen VHS-C tapes from past NSTAR flights. I recently upgraded to a new homebuilt Win7 system and on the same Newegg order I purchased a Diamond VC500 USB video capture device. However, I have been very dissatisfied with the hardware itself and the driver software. During the capture process it tends to drop frames frequently, abort the capture entirely, and the driver software does not have a way to set a maximum capture time - you must stop it manually, which means babysitting it or chopping off hours of blank screen at the end of the file. Plus the MPEG compression it uses is nasty and the other options are worse.

I don't need broadcast quality, but I'm not looking for the bottom end of the consumer market like this particular device appears to be. I'm guessing a PCI card would be superior to a USB/Firewire device. Any recommendations, esp. systems know to work on Win7?

I believe that the issue of quality is not USB or PCI but rather what method of encoding the device uses. The inexpensive devices use the processor in the PC to do the compression. This takes quite a bit of CPU power and if the PC is distracted doing other things it could cause dropouts ect. Other devices use hardware encoders on the device, these should not have capacity problems. Problem is I am not sure how you discover which encoding method a particular device uses.
I have a Diamond Wonder HD 650 PCI tv tuner card. In addition to the analog and digital tv tuner it has S video and composite video inputs for video capture. To be honest I have not used it in the capture mode from these inputs but I have successfully recorded off the air analog TV with it with no dropout problems. Which should be the same with regard to capacity. It also does a good job of recording off the air digital HD tv but this is already encoded.Jim Hannon

From: dvpatterson@comcast.net
Topic: 6365 Message: 6367

You might try a direct capture device, like the Pinnacle Video Transfer. (I purchased mine when woot .com had it up for ~$80.) It does direct-to- USB device MPEG -4 encoding, so you can record to a high-speed USB HD , then use your new computing power for editing. The only problem that I have with it is that it interlaces frames, which works well for DVD authoring, but requires some post-recording work to make it YouTube friendly. Otherwise, I've been very happy with the quality of the compression.

For computer-based capture, I've always used FireWire devices for full broadcast quality without any trouble, even 5 years ago. The biggest thing that helps there is to have a HD that's dedicated to the capture process (not just a partition), and make sure that the write speed can keep up with the specs for your selected capture device. While there is the consideration of available processor cycles for the compression, if the heads get moved off of the write position on the HD platter for some background OS process, you'll see drops for sure.

Hope that helps!

6368. Geiger counter

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-21 14:00:16 UTC
From: L. Paul Verhage
Topic: 6368 Message: 6368

If anyone is interested in a Geiger counter for near space missions, Electronic Goldmine is selling a kit for $79.95. It won't detect alpha rays, but is about half the cost of the Aware Electrojnics GM-60s that I fly.

Since it has a blinking LED display (along side the speaker), you could count the voltage pulses across the LED with a COUNT command.

Here's the link,
http://www.goldmine-elec-products.com/prodinfo.asp?number=C6979

Mark,

Thanks for mentioning that LPG can contain a considerable
fraction of butane, which I didn't realize.

More details, including a heating value comparison with natural
gas (almost all methane), at wikipedia:

6372. September Balloon Launch Opportunity....

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-24 22:02:55 UTC
From: Keith Kaiser
Topic: 6372 Message: 6372

Fellow Aeronauts,

As you may be aware 2010 is the 100th Anniversary of the Boy Scouts of America. The Heart Of America Council of the BSA will be holding a Centennial Celebration Sept. 24, 25, 26 near Bonner Springs, Kansas at Camp Naish. The expectation is for about 20,000 Cub Scouts, Boy Scouts, and Venturers to attend the long weekend event. This will be the second largest celebration in the country, surpassed only by the National Jamboree being held in July at Fort A.P. Hill, Virginia.

I have the honor to server as the Venturing Activities Coordinator for all four of the sub-camps that will be in operation that weekend. I'm very happy to say that Amateur Radio will be very well represented as will Amateur Radio High Altitude Ballooning. To that effort is the reason for this note. I need three more ARHAB groups to launch balloons on Sunday morning 9/26 in coordination with NSV's launch.

This would mean traveling to Bonner Springs, KS, coordinating your effort with the NSV representative, doing the launch with however many spectators are present, then doing your own recovery. However it also means a potential audience of 5000 to 10,000 Scouts and an opportunity to show, teach, explain, and recruit these same Scouts. The expense like the opportunity is yours, if you think your group would be interested please contact me asap for more information.

Near Space Sciences is interested.

We have done flights for scouts before and always was a good time and exciting too. I don't know if a local scouting group here will be doing anything on those dates or not.

Keith,

I might be able to come out there for the event...but a bit too early to tell what my schedule is. If I can't make it there, I will try to fly locally at the same time with a scouting group here. The only thing that would be needed would be a helium tank...any thoughts on whether you can do a group transport of tanks to the site as well as their return?

6376. what microcontroller - flight controller do you use

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-26 00:55:18 UTC
From: ccccrnr@aim.com
Topic: 6376 Message: 6376

what kind of flight controller / cut-down controller / camera-repeater controller does everyone one use?

Also what language do you program in(asmbler, C, C++, Basic, other) ?

I got my first Arduino (a Duemilanova) Friday, but had been thinking about getting PicKit 2 to use PIC18F's.
Just wondering what has proven well for others and what code may be out there for the routine parts of every flight?

Thanks,
Carlton Corbitt

I've traditionally used the PIC 16F series of controllers. I had planned on porting over to the Atmel series, but am in the process of building a ArduinoTracker instead.

I have used an SX-48 (from Parallax) on three flights. It works well controlling the cameras, sampling sensors and logging data. I used SX BASIC for it.
I am presently developing a new flight computer based on the Atmel XMEGA. It has more programming space, I/O, memory and lower power. Atmel provides a free C compiler.

Hi Carlton,

EOSS has used the Parallax Basic Stamp 1 & 2 for its DF beacons/cutdown
command receivers, but have migrated to the PICAXE for its latest such
beacon as well as the SamCam II rotating digital camera payload.

IMHO, the PICAXE lineup is every bit as powerful as the BSC line and
a darn sight less costly.

Hi Ron,
Might try rolling your own using a DJ-C1 and DJ-C4/5 HT pair with
a PICAXE running as a controller & IDer. Most HTs with crossband
capability don't have internal IDers, relying on the operator for
that job - brushes sideways with Part 97 repeater ID requirements.

I am still on the Basic Stamp 2p and have been using Stamp 2 variants for about ten years now. However, I am slowly migrating towards the Arduino platform. I have a project underway for 2010 that will use a companion WaveShield to act as a "talking APRS beacon", reading out location, altitude, course, and speed at intervals. After that's done, I'll work on replacing the Stamp with an Arduino. My C programming is a little rusty, so the progress is slower than I'd like.

I also have a few PICAXEs to play with too, mostly for simple stand-alone timers and such.

Carlton,

I've used Atmel Mega AVR and the Arduino (AVR chip with C routines) for balloons. As well as PIC, HC11 and HC05...all programmed in C or Assembly (and of course the Picaxe or Basic Stamp for small routines)....however, my current favorite has got to be the Cypress PSoC (second choice would be the Arduino or dedicated AVR). The PSoC has analog filter modules and other neat things on the chip which offloads processing power to do other things. The development system now comes with a free and very complete C compiler. Once you get used to the GUI of graphically routing pins and selecting the digital and analog modules, you'll find it's a very powerful micro.

Although I was set back a few months when I lost a good deal of my code and PC board files due to a home invasion theft of my computer last August, I have finally gotten the GPS-enabled multi-mode tracking transmitter using the Cypress PSoC back where it was and have improved the code along the way. I now have it doing the following modes: DominoEX, CW, Hellscreiber, RTTY and most recently have added PSK31. I'm very close to having it also do APRS packets....all of this with a small PSoC CY8C29466A chip. The newest PSoC 3 and 5 series are even more powerful but will probably not be easy to solder as they are a fine pitch pin package.

The thing I like about the PSoC is that you can turn a PWM square wave signal into a sine wave just by running it through the onboard band pass filter module.

what kind of flight controller / cut-down controller / camera-repeater controller does everyone one use?

Also what language do you program in(asmbler, C, C++, Basic, other) ?

I got my first Arduino (a Duemilanova) Friday, but had been thinking about getting PicKit 2 to use PIC18F's.
Just wondering what has proven well for others and what code may be out there for the routine parts of every flight?

Thanks,

Ron,

If you can get your hands on an old Icom IC32AT....it does a great job of cross band repeating....just takes a special sequence of touch tones to set it up...I believe the Joe at NSS also has used this radio in that fashion. They sometimes come up on eBay or hamfests.

From: L. Paul Verhage
Topic: 6390 Message: 6390

I put together a short video of the experiment with the Electronics Goldmine Geiger counter kit.

It runs off a 9V battery by boosting the voltage to 600 volts with a 555 timer and transformer. The resultsof this can be seen when a PICAXE counts 5 or 6 detections for each cosmic ray. I have screen shots form a oscilloscope that show this very well in the video.

6394. Geiger Counter

Yahoo group: GPSL (2009 — 2010)
Date: 2010-01-30 16:45:52 UTC
From: L. Paul Verhage
Topic: 6394 Message: 6394

I'm experimenting with the Electronics Golmine Geiger counter kit. It uses a 555 timer (set at 128 Hz) and small transformer to boost nine volts to 600 volts for the GM tube. Each time a cosmic ray passes through the GM tube, there are 5 or 6 voltage pulses of four volts high.

Here's the video so far, http://www.youtube.com/watch?v=lc0dirkliMo

I used a BalloonSat Mini flight computer to count the pulses and it worked well (it just needs to divide the count by 6). The kit cost me $70, so it's less expensive than the Aware RM-60 Geiger counters I use today.

However, I'd like to get rid of the pulses and smooth out the DC. So I'm looking for a .033 uF cap with a voltage rating of over 600 volts. I see Digi-Key carries them, but I'd have to pay $6 shipping on a 75 cent piece. Does any one local to Topeka have a cap like this in their junk drawer?

The time it takes to get the six pulses per detection is 48 ms. That means during that time, no other detection can be make (this is referred to as the GM tube's dead time). I'm wondering if I smooth out the voltage spikes with the cap across the GM tube if that will help shorten the dead time. compare this to the dead time of a RM-60 which is 20 ms (50 ms is not excessive for near space use, since the highest counts I've seen is 800 per minute - it becomes a problem as the dead time approaches 120 ms)

Electronic Goldmine sells a smaller GM tube suitable for measuring gamma rays. So after I complete this experiment, I'll look into building a kit around this tube for near space use. I think I can keep it to less than $50 - which will make it easier for schools to measure cosmic rays during a near space mission. I could also see it being used in robotics competitions (say simulating the clean up of a nuclear accident).

Hi Paul,

I was hoping to see how your corona abatement work with this HV circuitry
went in the video, but it seems that your link is for a hovercraft.

Corona discharge and frank breakdown can become a significant problem
at high altitude for any circuitry supporting over about 250V in air.
Fortunately, you have an altitude chamber with a viewing window that
will let you see if there's any corona issue.

Hi Paul,

That 8 ms rep rate is intriguingly close to the period of the 128 Hz DC-DC converter switching freq, so it appears that the 600Vdc supply may not be filtered at all. Is that what the 33 nF 600V cap is for? I'm sure I've got one in my junk box, but it would still cost some $$ to ship it to you. If you can dig up a stash of old tube-type radios or TVs, I'll betcha you could find what you need in the chassis (that's where my junk box got its start).

Otherwise, you could simply run that output signal thru a simple R-C low pass filter, with maybe a 10 - 15 Hz pole freq before it gets to the PICAXE - or you could run it thru a comparator to detect only the first, high-amplitude pulse. Or both.

If I had a schematic, I might be able to be of greater help.

Oh yeah - be SURE to run it up to altitude, looking for corona (dim blue glow) in a darkened room. If you find some, try filing off any sharp metal points carrying the HV and/or applying corona dope (thick, clear nail polish) to the offending points. If PWB clearance is shy, there may even be a frank breakdown, which will be a lot more obvious - and potentially fatal to LV parts nearby.

I wrote about this on my blog (nearsys.blogspot.com). Those pulses are from
the 555 timer. The dead time on the GM tube is around 50 ms, so there's
time for six 555 pulsesto show up.
I'd like to filter that out with a cap and see if it also helps to reduce
the GM tube's dead time.

From: Mark Conner
Topic: 6365 Message: 6400

Just to follow up on this......

I purchased an ASUS PCI-E capture card/TV tuner, hoping this would not only let me digitize my videos but add off-air TV capability to my computer. Unfortunately, anytime the video would glitch the captured file would become corrupted. On the advice of David Patterson and others, I got a Pinnacle Video Transfer device instead. This is a no-computer-required solution which will take composite or S-Video and audio and digitize it directly to a USB device such as a thumb drive or USB drive (must be FAT32 format). While this unit has its own idiosyncracies, it's working well for what I need it to do.

I would not put the capacitor across the gm tube itself. This could damage the tube by supplying excessive energy when the tube does fire. You really want is to filter the 600 volt supply then feed it to the tube thru a high value resistor. For example: http://www.sparkfun.com/datasheets/Sensors/Radiation/Geiger_Counter-v18.pdf notice the 10 meg ohm resistor. You need to limit the current into the tube to allow it to quench and prevent damage. Sounds like your circuit does this by supplying the voltage in pulses. If that is the case I would seriously consider redoing the power supply to make it more like the sparkfun circuit.Jim Hannon

Subject: Re: [GPSL] Geiger CounterI wrote about this on my blog (nearsys.blogspot.com). Those pulses are from the 555 timer. The dead time on the GM tube is around 50 ms, so there's time for six 555 pulsesto show up.I'd like to filter that out with a cap and see if it also helps to reduce the GM tube's dead time.PaulOn Sat, Jan 30, 2010 at 9:47 PM, Mike Manes <mrmanes@...> wrote:Hi Paul,
That 8 ms rep rate is intriguingly close to the period of the 128 Hz DC-DC converter switching freq, so it appears that the 600Vdc supply may not be filtered at all. Is that what the 33 nF 600V cap is for? I'm sure I've got one in my junk box, but it would still cost some $$ to ship it to you. If you can dig up a stash of old tube-type radios or TVs, I'll betcha you could find what you need in the chassis (that's where my junk box got its start).
Otherwise, you could simply run that output signal thru a simple R-C low pass filter, with maybe a 10 - 15 Hz pole freq before it gets to the PICAXE - or you could run it thru a comparator to detect only the first, high-amplitude pulse. Or both.
If I had a schematic, I might be able to be of greater help.
Oh yeah - be SURE to run it up to altitude, looking for corona (dim blue glow) in a darkened room. If you find some, try filing off any sharp metal points carrying the HV and/or applying corona dope (thick, clear nail polish) to the offending points. If PWB clearance is shy, there may even be a frank breakdown, which will be a lot more obvious - and potentially fatal to LV parts nearby.

I'm experimenting with the Electronics Golmine Geiger counter kit. It uses a 555 timer (set at 128 Hz) and small transformer to boost nine volts to 600 volts for the GM tube. Each time a cosmic ray passes

through the GM tube, there are 5 or 6 voltage pulses of four volts high. Here's the video so far, http://www.youtube.com/watch?v=lc0dirkliMo
I used a BalloonSat Mini flight computer to count the pulses and it worked well (it just needs to divide the count by 6). The kit cost me $70, so it's less expensive than the Aware RM-60 Geiger counters I use today.
However, I'd like to get rid of the pulses and smooth out the DC. So I'm looking for a .033 uF cap with a voltage rating of over 600 volts. I see Digi-Key carries them, but I'd have to pay $6 shipping on a 75 cent piece. Does any one local to Topeka have a cap like this in their junk drawer?
The time it takes to get the six pulses per detection is 48 ms. That means during that time, no other detection can be make (this is referred to as the GM tube's dead time). I'm wondering if I smooth out the voltage spikes with the cap across the GM tube if that will help shorten the dead time. compare this to the dead time of a RM-60 which is 20 ms (50 ms is not excessive for near space use, since the highest counts I've seen is 800 per minute - it becomes a problem as the dead time approaches 120 ms)
Electronic Goldmine sells a smaller GM tube suitable for measuring gamma rays. So after I complete this experiment, I'll look into building a kit around this tube for near space use. I think I can keep it to less than $50 - which will make it easier for schools to measure cosmic rays during a near space mission. I could also see it being used in robotics competitions (say simulating the clean up of a nuclear accident).

Hi Paul,

It appears that the pulsatile HV delivered to the G-M tube may be an ineffectual attempt to quench the secondary emission that would otherwise create extra pulses. See:

http://en.wikipedia.org/wiki/Geiger%E2%80%93M%C3%BCller_tube

Perhaps slowing down the 555 would help, although it would also back down on the max count freq at altitude.

Yeah, lacking a schematic, I'd assumed that there was a many-meg R in
series with the tube, across which the arc pulse signal is developed.
I'm guessing that the slight negative bias between the +HV pulses is
intended to quench the tube, but maybe not, or it's not doing the job.

Perhaps I should use a PICAXE-08M in place of the 555 timer. The PICAXE can then shut off when at a detection to let the tube quench. That would make a smart Geiger counter like it looks like Sparkfun is doing. The PICAXE could also do the calculations of counts per minute and send the data to a BalloonSat flight computer.

I'll send a copy of the schematic of the current circuit tomorrow (need to scan it).

The circuit connects the transformer to the GM tube with a diode and 100k resistor. So only DC pulses get to the GM tube.

When the GM tube discharges, it triggers the piezo speaker and darlington connected to the indicator LED.

Paul

From: Mike Manes
Topic: 6394 Message: 6405

Hi Paul,

Looking over the SparkFun device, I don't see any means for the uP to control the G-M tube HV bias; Q1-Q2 comprise a free-running ~50 Hz power oscillator driving a step-up xformer that feeds a voltage tripler, D2-D4. G-M tube discharge current is limited by R7-8 (11 meg). The R7-8 x C6 time constant is about 110 ms, which is a lot longer than the G-M tube quench time.

But I think you have a good idea to use the uP to control the HV supply. Not sure I've seen that approach taken before.

BTW, I still think you should run it thru your altitude chamber before flying it. Corona discharge could as a minimum ruin your data, if not your hardware. I've seen it happen!

I really believe that the Geiger tube in the electronic goldmine kit is self quenching and does not need any external power supply manipulation to properly quench. What appears to be the tube is on this page http://www.imagesco.com/geiger/geiger-counter-tubes.html It is listed as having a fill gas of Neon, Argon and Bromine. Bromine is the quench gas. All a self quenching tube needs to operate properly is a steady HV supply within the plateau region of the tube and a high value series resistor.
Here is another power supply circuit. I like this one because it is adjustable but it does have a lot of parts. http://pdfserv.maxim-ic.com/en/an/AN3757.pdfJim Hannon

Subject: Re: [GPSL] Geiger CounterHi Paul,
Looking over the SparkFun device, I don't see any means for the uP to
control the G-M tube HV bias; Q1-Q2 comprise a free-running ~50 Hz power
oscillator driving a step-up xformer that feeds a voltage tripler,
D2-D4. G-M tube discharge current is limited by R7-8 (11 meg).
The R7-8 x C6 time constant is about 110 ms, which is a lot longer
than the G-M tube quench time.
But I think you have a good idea to use the uP to control the HV
supply. Not sure I've seen that approach taken before.
BTW, I still think you should run it thru your altitude chamber
before flying it. Corona discharge could as a minimum ruin your
data, if not your hardware. I've seen it happen!

I've attached two of the pages from the Geiger kit. You'll see the 555 timer is controlled by C2 and R2 (there is no traditional R1 that you normally find in a astable multivibrator). R1 is a pull up reisistor for Q1, which operates the transformer. So C2 is charged and discharged through R2 (a 12k resistor). With C2 having a value of 0.47 uF, I get a frequency of 127.7 Hz. The period of the pulses is then .0078 sec, or 7.8 ms.

I just looked at the oscope this morning and see it's set to 5 ms per time division. So opps, the pulses are 4 ms apart. I need to double check my work, as this doesn't make sense when you look at the schematic.

From the oscope display I can see the tube is self-quenching. I'm wondering though if I can speed up the process by controlling the power. Right now its dead time is 50 or so ms. I'd like to knock that down.

There is a problem with the 600 volts in a vacuum. The display LED is constantly on as current jumps across the high voltage terminals. I'll cover them with hot glue to see if that helps.

Paul,
Quenching and dead time are sort of two separate things. When a particle strikes the tube it creates a cloud of charged particles along the path. The high voltage applied to the tube causes the charged particles to drift to the electrodes generating a current when the collect on the electrodes. Until these particles all drift out of the tube the tube is dead to new pulses. Just because you cannot tell the difference between the current geneated by the first particle from any other particle. The time to dirft depends on the distance between the inner and outer electrodes and the applied voltage. The higher the voltage the faster the drift or shorter the dead time. The smaller the distance between the electrodes the shorter the dead time. But you can't go too high or the tube will arc over. Reducing the tubes voltage will quench the tube but it actually increases the dead time. I believe what you are seeing with the multiple pulses in your counter is that the high voltage is applied in pulses. Each pulse does not last long enough to clear the charged particles from the tube, so they stay creating current for several voltage pulses. A steady high voltage applied to the tube will clear the charged particles faster thus reducing the dead time. Quenching is preventing the drifting particles from striking other atoms and causing an avalanche effect. The quench gas absorbes the collisions without generating other ions. The idea of turning off the high voltage for quench prevents collisions by reducing or stopping the drift of the charged particles. Then you wait a loong time for all the ions to recombine and setttle down.Jim Hannon

Okay. So I want to add a cap across the GM tube to filter out the pulses.
I think I should also increase the pulse frequency in order that I can use a
smaller value cap.

If I remember right, someone said I should also include a resistor with that
cap to limit current?

Hi Paul,

Hot melt can work as a conformal coating provided you heat the target surfaces up to the glue melt temperature and you make SURE there are no air bubbles in or under the coat. Clear nail polish or heavy acrylic paint is easy to apply properly - the idea is to get all the air and other gasses far enough away from the high voltage points that they are in a low enough E-field gradient to prevent avalanche. Even a tiny air bubble in HV insulation can support corona that will eventually eat its way thru, leaving a carbon track behind.

Hi Paul,

I finally got the 2x 348x480 .bmp's that got posted on Yahoo - pretty low res for schematics, but I think I've figured it out:

The HV bias for the G-M tube is RC filtered by R3 (100 K) and C3 (10 pF), yielding a 1 usec time constant. The charge on C3 will drain off R4 & R6 (4.7 meg || 10 meg) with a TC = 32 usec or until the tube fires, and then its <1.8 uJ of energy is dumped, creating a click in the speaker and blink in the LED. After that, the tube is unbiased until the next +HV pulse from the 125 Hz power oscillator. So its fastest count rate is 125 Hz - a bit less than the rate you expected. Now, I'm not sure why you get a string of 5 pulses, unless the plasma in the tube takes over 64 msec to decay (quench). So your scheme to shut off the oscillator for a bit (< 64 msec) after you get a hit will do the trick, but that would slow your max count rate down to < 16 cps or < 1000 cpm.

Hi Jim,

In the absence of an E-field, the electrons and ions that comprised the plasma will spontaneously recombine due to electrostatic attraction. The time necessary for that to happen is a function of the volume and density of the plasma particles, and the presence of the same E-field that created the plasma will slow that process down. Now, given the puny value of the C3 filter cap (10 pF), I'd not be surprised if its voltage took a dive as soon as the rectifier went into reverse bias - simply due stored charge recovery; the 1N7000 isn't a fast recovery diode - not enough to totally discharge the cap, but enough to make the G-M tube more sensitive during the charge cycle from the oscillator.

I'm thinking we're boring most of the GPSL crew to tears with this thread, so maybe we oughta take it direct?

Mike, Jim, and Paul,

I'm really enjoying the discussion. Sort of thing that an old arks and sparks experimental physicist likes to think about. If you do go direct, I'd like to read along.

Thanks,

Howard (hlbrooks@ depauw.edu)

Same here, sensors used on AHABs are appropriate content here, but
let's keep the subject as Geiger Counter so that others can delete /
filter easily as they wish. I am enjoying the conversation and
thoughts about improving the sensor as well.

Subject: Re: [GPSL] Geiger Counter

Hi Jim,

In the absence of an E-field, the electrons and ions that comprised the plasma will spontaneously recombine due to electrostatic attraction. The time necessary for that to happen is a function of the volume and density of the plasma particles, and the presence of the same E-field that created the plasma will slow that process down. Now, given the puny value of the C3 filter cap (10 pF), I'd not be surprised if its voltage took a dive as soon as the rectifier went into reverse bias - simply due stored charge recovery; the 1N7000 isn't a fast recovery diode - not enough to totally discharge the cap, but enough to make the G-M tube more sensitive during the charge cycle from the oscillator.

I'm thinking we're boring most of the GPSL crew to tears with this thread, so maybe we oughta take it direct?

From: L. Paul Verhage
Topic: 6394 Message: 6419

Success. It appears the Geiger counter is discharging around the two negative terminals at the ends of the tube. I couldn't see a corona, but after coating the ends with hot glue, the Geiger counter has stopped producing a constant output at vacuum.

We get around 18 CPM at Topeka level and 18 CPM in 30 inches of mercury vacuum.

I'll get a picture and post it on my blog. I have video of the test and I'll edit it into something worth posting by ther weekend. I'm sure no one wants to watch 5 minutes of a Geiger counter LED blinking.

Paul

Paul,

How does the background count rate for the Aware RM-60 compare? We're at almost the same altitude and your count rates are a little higher than our RM-60 data.

Alternatively, do you have good measurements on the GM tube volume. Perhaps the RM-60 is a little smaller.

Success. It appears the Geiger counter is discharging around the two negative terminals at the ends of the tube. I couldn't see a corona, but after coating the ends with hot glue, the Geiger counter has stopped producing a constant output at vacuum.

We get around 18 CPM at Topeka level and 18 CPM in 30 inches of mercury vacuum.

I'll get a picture and post it on my blog. I have video of the test and I'll edit it into something worth posting by ther weekend. I'm sure no one wants to watch 5 minutes of a Geiger counter LED blinking.

Hi Jim,

In the absence of an E-field, the electrons and ions that comprised the
plasma will spontaneously recombine due to electrostatic attraction. The

time necessary for that to happen is a function of the volume and density
of the plasma particles, and the presence of the same E-field that created
the plasma will slow that process down. Now, given the puny value of the

C3 filter cap (10 pF), I'd not be surprised if its voltage took a dive as
soon as the rectifier went into reverse bias - simply due stored charge
recovery; the 1N7000 isn't a fast recovery diode - not enough to totally

discharge the cap, but enough to make the G-M tube more sensitive during
the charge cycle from the oscillator.

I'm thinking we're boring most of the GPSL crew to tears with this thread,
so maybe we oughta take it direct?

The GM I'm using now is claimed to be sensitive and can only detect betas and gammas (it doesn't have a mica window like the RM-60). The tube is longer, but narrower than the Aware unit.

I'll make measurements tonight and compare them. I'd like to fly both together to see how many alphas there are in near space.

Paul,

Alphas from radioactive decay are not very energetic, but stratospheric alphas, estimated to be 10-12% of all cosmic rays are most likely to be very energetic. I like the idea of flying both detectors, but I worry that the premise that the Electronics Gold Mine geiger only sees betas and gammas is assuming low energy alphas.

It is an interesting question. What happens if two AWARE RM-60s are flown with one having the mica window shielded by a metallic absorber similar to the walls of the GM tube in the RM 6. I might be able to do this using the carcasses of the RM-60s that floated in Lake Erie a couple of years ago.

Good for ya, Paul! Now, low-energy corona is often hard to see. We used to completely darken the lab to see it and let our eyes dark-adapt a few minutes. But even the dim stuff can be evil if allowed to persist for a while. Glad you got shut of the symptoms - but it may still be lurking in the background, gradually nibbling away at neighboring polymers.

And I was stunned by the number of GPSL folks who've been reading this tedious, geeky thread. C'mon - git a life! :=}.

Surely you are familiar with the concept of "Intelligence by Association";
Yall are making the rest of us look smart, cause now we know some new words !
And if we practice, we can use em in complete sentances !

Otherwise I'm mighty impressed at the depth some of this goes to...
I'd say we are hanging with a pretty sharp crowd,
and mighty lucky that yall let us in on such detail.
I've learnt a lot more about Geiger Counters than I ever expected to.

Please - don't let us hold you back..!.. Carry on !
73 for now /;^)

I ran both GMs in my home office last night and have attached the spreadsheet. The columns include the raw counts for both detectors and the modified counts for the Goldmine counter. Recall that there is 6 pulses per detection and occasionally 5 in the Goldmien detector. I divided the raw count by six and looked at the remainder to determine how many missing pulses there were. Then I added those back to get a final, corrected count.

The Goldmine GM detected a lot more radiation, but has a narrower spread across the values (lower standard deviation) when the two counters are scaled.

Does anyone know how to make Excel plot the distribution of counts? I'd like to show the distribution plots. In the final columns I'm putting this data together by hand. I don't mind this, but I do have a real job and and school in the afternoons.

I've also attached a photo of the glued GM tube. It ain't pretty.

I'll purchase the smaller GM tube from Goldmine and see about operating it from a PICAXE-08M. I can experiment with electronic quenching (if it works) and with the best pulse rate. Perhaps by adjusting the PWM signal from the PICAXE, I can change the standard deviation.
Finally, my wife and I will be completing school in December (11 months). I'd be interested to hear what the job market is like at universities.

All for now,
Paul

Oh, the Goldmine tube is 3.5 inches long and 0.4 inches in diameter. The RM-60 tube is 1.5 inches long and .6 in diameter. The volumes are the same, but thre should be more frontal area for cosmic rays to pass through on the Goldmine tube.

Note, these numbers should be right, but I'm trying to recall them from last night. I can't find my notes, so it's possible I'll give you updated numbers tomorrow.

Found the measurements.

The RM-60 tube is 1.5" long and 0.6" in diameter
The Goldmine GM tube is 3.6" long and 0.4" in diameter.

The RM-60 has 0.42 cu in volume and the Goldmine has 0.45 cu in volume.

The cross area of the RM-60 is 0.9 sq in and the Goldmine is 1.44. That
makes the Goldmine 1.6 times larger.

Paul,

The histogram function is available on Excel, if you have the data analysis tool pack, which Microsoft views as an add-in. The online help can assist you in binning the data and making the plot.

I've attached a spreadsheet with the histogram plotted on separate worksheets, although I've put all of the raw bin data on the front sheet.

Finally, my wife and I will be completing school in December (11 months). I'd be interested to hear what the job market is like at universities.

All for now,
Paul

The thing to do may be to compare the counts while using a check source on the ground. That should let you build an intensity profile of alpha sensitivity. There are, of course, quite a few alpha particle emitters out there; the trick may be getting something pure enough, and not contaminated with decay daughter products, to get a reasonably pure, single energy alpha particle output.

Note that energetic alphas may produce secondary betas (or even gammas) when encountering some materials. For that matter, some energetic alphas may even knock secondary neutrons out for the rare nucleus collisions (e.g., with Beryllium), and neutrons can do all sorts of screwy things (That's technical jargon there!). :*)

Ohoh, why is it I think some of this discussion may have just made your payload package a LOT more complex? :*)

Note that exempt check sources are available from a variety of places (e.g., United Nuclear, I think), usually for not too much money, and some improvised check sources may be even cheaper (e.g., Fiestaware orange dishes, and vaseline glass, which contains Uranium Dioxide).

> Paul

Dave

P.S. Yes, I have a bag of vaseline glass marbles, and could even send you some, but I don't currently have a meter, so I can't tell how active they are.

I have a piece of orange Fiesta Ware inside my near space environmental test chamber. Great stuff. The Goldmine detector picks up a significant count near the china, so I suspect there's lots of decay products inside the glaze. If I recall, the alphas from Uranium are 4.5 MeV, as are the alphas from its first decay product, thorium.

I had a bad experience with United Nuclear back in 2003-2004. They cashed my check, but never sent my product. I'd be curious if anyone else has dealt with them.

It's no problem making the experiments more complex. It gives you an excuse to fly again. Besides, you never know what you're going to learn.

One apparent issue is how sensitive each detector is to the same radiation. That's a good reason to purchase a pure radiation source. It's like of like starting a project at home and using it as a justification to purchase new tools.
;)

6432. Time-base corrector rental

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-04 21:16:18 UTC
From: Mark Conner
Topic: 6432 Message: 6432

I've found a new snag in my VHS-C video capture project. It appears that several of my tapes have segments where the sync signal is so messed up the capture device can't deal with it and aborts the capture. With all the RF hits and mechanical shaking the camcorder went through at the time, I guess it's not too surprising that the video signal isn't too clean.

From what I could find with Google, it appears a time-base corrector may solve these problems. It effectively reproduces each line or frame with a properly-formatted sync that will hopefully let the capture device record properly. It should also produce a cleaner video copy as a bonus.

Does anyone on the list have a TBC that they'd be willing to loan out for a few weeks? I'm more than happy to pay a reasonable rental fee and insured/tracked shipping both ways.

Hi Mark,

Could you not record several segments, eliminating the bad areas, then splicing the segments together digitally in the software?

You are correct, the Time-base corrector (TBC) will help provide stability to your video. We designed and sold these along with our cameras and video tape recorders during my days at Ampex Corp in Redwood City, CA. This was all professional grade equipment. The TBC digitally corrected the time between horizontal sweeps and inserted it's own sync signals. You could sync the TBC and the video player to house sync for playback on the air.

You can look at some of the long-standing video production houses in your area for use of their TBC. Local news stations that have been around a while and companies specializing in making of commercials may still have these. In the past decade, most video has gone digital, so TBCs are not used as much, but a lot of older video material is still on tape.

Cameras and video tape machines that brought you the 1979 Lake Placid Olympics were machines I worked on right out of college. Man that was long ago!

6435. Re: [KNSP] Time-base corrector rental

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-04 23:34:12 UTC
From: Mark Conner
Topic: 6433 Message: 6435

Harry,

Yes, however, on at least one tape the chaos after burst won't capture for a couple of minutes due to the glitches. I have a couple of other tapes where the RF from the APRS beacon glitches the video every 30 seconds. The video playback on screen isn't that rough, but apparently the sync is so ragged that the capture device gives up. If I want to record "around" the glitches, this means babysitting the playback and stopping/restarting the tape frequently. More trouble than I really want to go to.

There are some "pro-sumer" TBC units for about $200. Commercial units are four figures. I found a place that rents them online, but they a few hundred $$ per week. I'm hoping someone on the list encountered the same thing digitizing their home movies and has a prosumer unit sitting around.

The units do pop up on eBay from time to time and if I can snag one at a reasonable price I'll get it for this project and resell it later.

As an aside, while we're on the subject of video, I got my wife a Kodak Zi8 to get video of the kids. It will do HD video at 1080p/30fps or 720p/60fps (also standard-def equivalent). The Zi6 is a similar unit but uses AA batteries (preferable for balloon use, I think) and does not have image stabilization. The Zi6 can be had for under $100 and should produce excellent video - the Zi8 video is outstanding for a unit in its price class. Likely equal or better than the Flip units. Records to SD cards.

Hi Mike,

Thanks for the tip about contacting a video production company. Dunno if they'd loan/rent one out for a while, but the worst they can say is no. I have a passing ham acquaintance who's a tech at a local TV station, so I might see if that angle will work.

Hi Mark,

I was thinking more like taking your equipment to them and playing
through their system in off-hours. I don't think anyone making a
living with this stuff would let you take a TBC home, :) but you might
be able to talk them into the effort there on site. If you have a
friend at a local station, your best bet likely might be to get some
time there to dub your tape and even do some editing with their
equipment.

6438. LORAN-C General Information - USCG Navigation Center

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-08 20:00:56 UTC
From: Mike Manes
Topic: 6438 Message: 6438

The mid-continent range of the LORAN-C system is going QRT about
12 minutes from now. I'm monitoring 100 KHz as we speak; hearing
good signals at S8 on my IC-735 and G5RV.

http://www.navcen.uscg.gov/loran/default.htm

EOSS flew a LORAN-C onboard APRS reporting beacon payload
on several flights in the early '90's, and it did work fairly
well once it managed to get a 3-station lock - which was
a "sometimes" thing. It got mothballed after we got our
first GPS, a huge Magellan power-hog of a board that was
almost as picky as LORAN-C in getting a lock before launch.
But that was then - and that's a good thing.

A few LORAN-C stations in the N Pacific and NE US-CN coast will
remain operational until this October. I wonder what that spectrum
will be used for afterwards - any ideas?

Well, it's now 1952Z on 8 Feb 10, and 100 KHz just went quiet.
Hasta la vista, old friend.

6440. Launch Announcement: BallastHalo 4 - Pinhole Floater + Ballast Tank test 15:00UTC 13/2/10, UK

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-10 16:10:09 UTC
From: James Coxon
Topic: 6440 Message: 6440

Hi all,
Launch announcement about the upcoming launch of BallastHalo 4, the 4th launch in a series to test ballast tanks and pumps in anticipation of a trans-atlantic attempt (AtlanticHalo - http://spacenear.us/wiki/).

Launch Date: 13/2/10
Launch Time: 15:00UTC
Launch Site: EARS, Cambridgeshire, UK (52.2511, -0.0927)
Payload: ATmega328 with Arduino bootloader on custom PCB, Radiometrix NTX2 10mW 434.075Mhz radio, Lassen IQ radio, 3x DS18B20 Temp Sensors, Photocell, Williamson peristaltic pump and 500ml ballast tank (ballast = ethanol/methanol)
Balloon: 1500g He, pinhole (1.5mm) vent -> aim for float @ ~20km altitude

You can track the flight: http://spacenear.us/tracker with conversation on #highaltitude on irc.freenode.net

Currently looking for additional listening stations in S. England and N. France as potentially the payload could cross the channel, please get in contact if you can help out - all that is required is a 70cm SSB capable radio and a computer to decode. Telemetry can be automatically decoded and uploaded using dl-fldigi (http://code.google.com/p/dl-fldigi/)

For more info see:
http://www.pegasushabproject.org.uk/wiki/doku.php/missions:ballasthalo:ballasthalo4

6443. 2/13 HAB Flight

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-13 23:31:38 UTC
From: Pete Lilja
Topic: 6443 Message: 6443

I assisted W0GRB today with a HAB flight. It went off with nary a hitch (except one little glitch when he bumped the knob on his D7 and changed his call sign to X0GRB rather than W0GRB). The balloon hit 97,000' and change and we made an easy recovery off a very snowy cornfield near Independence, Iowa.

I had read over the last couple of years that these latex balloons are visible while at altitude. I never really believed it. Today, however, was a bright sunny day and at one crossroads where we stopped to figure a route to touchdown we took the time to look as the balloon was nearly directly above us at 97,000' +. We were actually able to see it! Some with younger eyes than mine saw it unaided and I was able to pick it out with binoculars! I am still surprised by that. One of our group, Larry, KC0KTV, was looking at it and it disappeared. I checked the radio and sure enough, it had burst. Larry essentially saw the balloon burst!

A very good day for the guys of http://nixhab.com/

Pete:
Glad to hear about the flight and your first experience seeing a balloon at altitude.
I've seen dozens of latex balloons naked eye up over 90k feet. It helps if you conduct the chase so that the sun is at your back.

My 24' black solar tetroons are not only visible, they are obvious (well, sorta) late in the day when at their ~54k feet MSL cruising altitude.

best

From: Zack Clobes
Topic: 6446 Message: 6446

I'm now taking volunteers and requests for sessions at the 2010 GPSL in Hutchinson. If you are interested in presenting, please include the following in your response:

1. Topic (5 words or less)

2. Short description of your presentation (2 sentences or more)

3. How much time do you expect the presentation and related questions to take?

4. Do you have a preference of when you present?

5. What resources will you need for your program (projector, computer, DVD, tables, etc)?

6. A cell phone number for the presenter for questions or coordination.

If you are not interested in presenting, but would like to see someone else speak on a specific topic, I'd be interested in hearing your suggestions.

http://www.officemax.com/catalog/sku.jsp?productId=prod1910035

http://store.kodak.com/store/ekconsus/en_US/pd/Zi6_Pocket_Video_Camera/productID.145116700

This camera is on sale at half price at OfficeMax ($80). It uses 2 AA batteries rather than an internal Li-ion, so it can be powered by Energizer L91s. My wife has the next step up (Zi8) and we get good results with it.

This will shoot 720p video at 60 fps, which might be good for taking some of the motion blur out. I have not yet tested our Zi8 to see if it will shoot 2+ hours of video at one time but imagine it will. The Kodak Zi6 rates pretty favorably compared to the Flip cameras and this is a very good price on it. I will likely be picking one up myself - even if it doesn't work as a balloon camera for some reason it is great for more conventional uses.

Subject: [GPSL] GPSL Call for Presenters

Topic: High Resolution Balloon Borne Spectrometer

Descrition: This instrument is for understanding atmospheric chemistry, it is a CCD optical spectrometer with multi wavelengths. It is a solar occultation instrument that will measure the trace constituents of the atmosphere by measuring the absorption of sunlight. It requires a sun tracker on a stabilized platform. The instrument measures the amount of H2O, O3, CO2, CO, CH4, N2O.

Time: 45 minutes

I'm now taking volunteers and requests for sessions at the 2010 GPSL in Hutchinson. If you are interested in presenting, please include the following in your response:

1. Topic (5 words or less)

2. Short description of your presentation (2 sentences or more)

3. How much time do you expect the presentation and related questions to take?

4. Do you have a preference of when you present?

5. What resources will you need for your program (projector, computer, DVD, tables, etc)?

6. A cell phone number for the presenter for questions or coordination.

If you are not interested in presenting, but would like to see someone else speak on a specific topic, I'd be interested in hearing your suggestions.

6451. Balloon Visibility

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-15 21:07:51 UTC
From: Pete Lilja
Topic: 6451 Message: 6451

I mentioned to my brothers our having seen our last balloon at 97,000'. I didn't see it unaided but others reported that they did. My shooting enthusiast brother responded with this:
*
I did a little multiplying and dividing and determined that seeing a 28' diameter balloon at 100,000' is the same as seeing a one tenth of an inch diameter hole at 100 yards. I used that because I know it isn't possible for almost anyone to see a .22 caliber bullet hole at 100 yards unaided. And a .22 hole is over twice as large in area as a .1" dia. hole.*

My only explanation is that the uncolored latex being illuminated by bright sunshine gives enough contrast to make it visible.

What are the thoughts of the HABists on these lists?

Pete

I consider myself to have pretty good (corrected) vision, and I can't reliably see a .22 at 25 yards.

However, I have seen a couple of balloon "stars" with the naked eye. I did watch a burst and I don't remember for sure, but I think it was through an SLR zoom lens or maybe a (weak) binocular. What I remember was seeing a white dot, and then very suddenly the dot became blurry, and then disappeared. The whole thing probably happened inside of a second or maybe two, but it was definitely visible.

Here's a couple of notes that I made about our 2003b flight:

- While watching the balloon from the ground, it appeared that the balloon was moving erratically, especially in the wrong direction. We finally decided that perceived motion at that range (85,000'+, directly above us) is not necessarily accurate. Initially, it appeared to be moving in the opposite direct that it really was, and later it appeared to be moving in short jerky movements. I think cloud movement, as faint as they may be, will inhibit much of any ability to determine direction of flight.
- If we intend to watch the balloon from the ground, especially in groups, some sort of tripod should be set up for the binoculars/monoculars. It took quite a while to find the balloon in the binoculars, and it was very difficult to try to hold them steady.

This is simple,

To your eye it is a point light source.

Ask him if he has ever seen a star?

There is something that is a thousand times smaller than that angle of
resolution the balloon provided you. yet you can see thousands of stars.

I agree, Joe. Thanks for the simple answer / response.

This is another example of people seeing the world from their own particular viewpoint. While the math involved is an interesting comparison is size - to me (from my perspective / viewpoint!) this exercise is more telling of how different people view the world by using their own experiences. My education is social science rather than hard science. My brothers' perspectives are more earthly than stellar science. We all see things from a different vantage.

See how much fun HABing can be! It encompasses everything!

Pete

From: Dominick Marrone
Topic: 6449 Message: 6456

Mark Conner,

Doesn't the video camera require stabilized ARHAB satellite orientation otherwise, camera/video will record 2-hours of constant spin and sway?

Q: What methods do you or GPSL use to stabilize the balloon satellite from rotation and/or pendulum swing?
i.e. Passive magnetic (in-line with N-S poles), active torque coils, mechanical absorbers: springs, boom, etc.?

Q: What type of orientation sensors (MFR/part number) do you use to establish a given orientation of ARHAB satellite?
Sun sensor, earth horizon sensor, other?

Once the ARHAB satellite rotation and pendulum swing is stabilized:
Q: What combination of: orientation sensor or other method do you use with uP controlled servos to actually point video camera at various earth or space targets?

Q: Do you or GPSL group have any literature/white papers on the subject of ARHAB satellite stabilization and attitude control methods?

The camera doesn't require stabilization to get decent video, though it would improve things considerably. I have quite a bit of video with vomit-inducing rotation, but also a lot with relatively gentle yaw rates. Things normally settle down during ascent pretty well after the initial launch chaos. Descent, OTOH.....

A while back I took a (brief) look at what could be done to stabilize a camera for a balloon flight. One approach would be to use an IR horizon sensor like those used for autopilots on R/C aircraft. This could give you what's necessary to keep the camera level to the horizon. Processing the data quickly enough to avoid hysteresis might be fun, but apparently it is possible. http://www.fmadirect.com/detail.htm?item=1489§ion=20

Once level, azimuth/elevation commanding could be done - azimuth would likely require an electronic compass to determine. An IMU good enough to go two hours without drift might be out of budget.

EOSS used an electronic compass as I recall, commanding a motor or servo. I don't know if the compass was tilt-compensated or not. Mike?

Some applications definitely need to be looking a specific direction. And for that, I don't feel that a simple IMU could withstand the rapid spinning and turbulence. However, if you JUST want to stabilize the video, I'd consider using a simple single-axis yaw rate gyro to drive a motor.

With a single rate gyro, your direction would gradually change over time, but I think it would be sufficient to eliminate the need for a Sick-Sack. This would have the advantage that throughout the flight, you would get different views.

I'm missing something, Joe. How was that stability achieved?

Pete, KC0GPB

OOps,,

sorry,

Wow I can't seem to find the video that showed the outside of the
payload, grrrr. I thought that was it. but that did show the
stability nicely from the payloads point of view.

How we did it is in this un finished page of the story for that flight.
it's at,

http://www.qsl.net/wb9sbd/nss-45.html

Sorry,,

Whew! I'm glad I wasn't missing something really obvious!

Calm winds are about as simple as possible...

Pete

Hi Zack,

EOSS would like to provide a presentation at GPSL. Here□s the data you wanted.

1. Balloon Flight Ionizing Radiation Estimate

2. Introduction to ionizing radiation in the upper atmosphere and an estimate of the dose received by two biological payloads on EOSS-149 during 106 minute flight to 74k ft.

3. 30 minutes

4. No preference as to presentation order.

5. Power Point-equipped computer and projector & screen

6. (303) 870-2802

Our presenter is Jim Langsted, KCØRPS.

73,

Nick Hanks, NØLP

EOSS GPSL Coordinator

To: Group GPSL
Subject: [GPSL] GPSL Call for Presenters

I'm now taking volunteers and requests for sessions at the 2010 GPSL in Hutchinson. If you are interested in presenting, please include the following in your response:

1. Topic (5 words or less)

2. Short description of your presentation (2 sentences or more)

3. How much time do you expect the presentation and related questions to take?

4. Do you have a preference of when you present?

5. What resources will you need for your program (projector, computer, DVD, tables, etc)?

6. A cell phone number for the presenter for questions or coordination.

If you are not interested in presenting, but would like to see someone else speak on a specific topic, I'd be interested in hearing your suggestions.

Hi Dominick,

EOSS's de-spun ATV payload uses a 2D electronic magnetic compass for
an azimuth reference, and a servo-driven camera platform, driving against
the inertia of the bulk of the payload mass to hold an ATV camera coarsely
aimed at a constant heading. It works pretty well eliminating the "mal
de mel" sensation felt by some when viewing unstabilized real-time TV.
Provisions for remote control of azimuth and elevation setpoints are
built in, but so far, we've not incorporated a remote control link.

See: http://www.eoss.org/hardware/spin_atv.htm

The camera doesn't require stabilization to get decent video, though it would improve things considerably. I have quite a bit of video with vomit-inducing rotation, but also a lot with relatively gentle yaw rates. Things normally settle down during ascent pretty well after the initial launch chaos. Descent, OTOH.....

A while back I took a (brief) look at what could be done to stabilize a camera for a balloon flight. One approach would be to use an IR horizon sensor like those used for autopilots on R/C aircraft. This could give you what's necessary to keep the camera level to the horizon. Processing the data quickly enough to avoid hysteresis might be fun, but apparently it is possible. http://www.fmadirec t.com/detail. htm?item= 1489?ion=20

Once level, azimuth/elevation commanding could be done - azimuth would likely require an electronic compass to determine. An IMU good enough to go two hours without drift might be out of budget.

Joe:
A floater balloon does not have to be a giant PE (polyethylene) balloon. The UTARC 'Spirit of Knoxville' balloons were less than 1000 cubic feet, and not more difficult to launch than a 1500 gram latex balloon. I am getting some downlooking video from a floating balloon digitized and will soon be uploaded on to YouTube so that people can see just how moderate the balloon dynamics are at float.

best

Provided, of course, that it's floating in stable air, i.e., absent strong shear, rotors, etc., e.g the one where the on-board video showed the payload ABOVE the inflated balloon!

6473. I still need help in September

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-19 14:49:26 UTC
From: Keith Kaiser
Topic: 6473 Message: 6473

Fellow Aeronauts,

Paul Verhage and Bill Brown have both stepped up and offered to help the Boy Scouts of America celebrate their 100th year in service to youth by launching a special Centennial balloon this September. I still need one more group to help out. Please read my original posting below and if you will be in the area or can be in the area that day please let me know as soon as possible.

Changes in the original note include the date. Instead of Sunday morning it will be Noon on Saturday 9/25. Logistics of getting your gas to the launch site are still being worked on. I doubt very much the launch team will be able to join the recovery team. In fact I would prefer you stay in camp and show the tracking of your balloon on a laptop, projection or whatever you can think of. I'm trying to arrange to have completely separate teams to do the chase and recovery.

Original Post:

As you may be aware 2010 is the 100th Anniversary of the Boy Scouts of America. The Heart Of America Council of the BSA will be holding a Centennial Celebration Sept. 24, 25, 26 near Bonner Springs, Kansas at Camp Naish. The expectation is for about 20,000 Cub Scouts, Boy Scouts, and Venturers to attend the long weekend event. This will be the second largest celebration in the country, surpassed only by the National Jamboree being held in July at Fort A.P. Hill, Virginia.

I have the honor to server as the Venturing Activities Coordinator for all four of the sub-camps that will be in operation that weekend. I'm very happy to say that Amateur Radio will be very well represented as will Amateur Radio High Altitude Ballooning. To that effort is the reason for this note. I need three more ARHAB groups to launch balloons on Saturday afternoon 9/25 in coordination with NSV's launch.

This would mean traveling to Bonner Springs, KS, coordinating your effort with the NSV representative, doing the launch with however many spectators are present, then doing your own recovery. However it also means a potential audience of 5000 to 10,000 Scouts and an opportunity to show, teach, explain, and recruit these same Scouts. The expense like the opportunity is yours, if you think your group would be interested please contact me asap for more information.

Fellow Aeronauts,

I'm please to announce I now have a complete team (plus one) for the Centennial Celebration launch.

The following teams have agreed to be there;

Paul Verhage
Bill Brown
Marc Conner
Near Space Ventures
Michael Willett and Doug Loughmiller from ARBONET

More details on this historic launch will be coming soon.

6476. Clearing up a Couple of Misconceptions

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-20 17:26:06 UTC
From: L. Paul Verhage
Topic: 6476 Message: 6476

I was thinking about these topics earlier this week and thought they ought to be cleared up. So if you'll permit me.

Most people are familiar with the concept that motion is relative. This means that motion to one person looks just the opposite to another person who is not sharing that motion. It's all a matter of your frame of reference.

When we discuss things like the ascent rates and maximum altitudes of a balloon, we really should be discussing these issues in their more accurate frame of reference, that of the balloon. In reality, the balloon is remaining still and the earth (along with the atmosphere which is firmly attached to the earth via gravity) is falling. This occurs because when we put helium into a balloon, we're removing it from the earth and its atmosphere (I'll refer to these as the earth-atmosphere system). When you remove low density material from the earth-atmosphere system, you're increasing its average density. Recall that dense objects can sink and less dense objects can float. The denser earth-atmosphere wants to sink after it remove its helium. And as long as the filled balloon is firmly attached to the earth's surface (via gravity), like by a person holding the balloon's load line or by tying the load line to a helium bottle, the balloon will hold up the earth. So those of you who are holding the filled balloon before launch, you're really holding the earth-atmosphere up. Think about that next time.

Once the balloon is no longer held to the earth, the earth-atmosphere falls away. As the earth and its atmosphere fall away, the balloon is surrounded by less and less dense air. The balloon expands as a result. Since the helium is trapped inside the balloon, there can be no further change in the earth-atmosphere's density and it falls away at a constant rate that is dictated by the friction of the air around the balloon. The atmosphere, which remember is firmly attached to the earth, can only slide pass the balloon at a limited rate. Friction is why the earth does not fall away from the balloon infinitely fast. Many of you have no doubt noticed that at some where around 30-40,000 feet, the balloon appears (and let me stress appears) to rise faster. This is the result of the earth-atmosphere slipping around the balloon faster because of changes in air density and balloon size. This is pretty obvious if you recall that the force of friction is based on factors like surface area and density.

At the point where the atmospheric pressure around the balloon is low enough, the balloon bursts and releases its helium back into the atmosphere. This mixing of helium back into the earth-atmosphere system decreases its average density, causing the earth-atmosphere system to float back up to the balloon. The air rising around the balloon payload makes it tumble (due to turbulence) and inflates the parachute. The mixing of the

balloon's helium with the atmosphere occurs very rapidly and therefore, the change in the density of the earth-atmosphere is very fast. This makes the earth-atmosphere begin to rise very quickly. At the earth-atmosphere rises back up to the balloon, the air becomes denser and the parachute creates more drag, slowing the ascent of the earth-atmosphere. Therefore, we see the initial ascent of the earth-atmosphere is very fast at the start, but over time, the ascent rate slows down until the balloon and earth make contact. At that point, the earth-atmosphere system and balloon are back in equilibrium and the motion comes to an end.

Now, since the days of the Greeks, we've known the world is round or spherical. There is no friction between the earth-atmosphere system and outer space. So when you go on a balloon chase, your car tires are pushing the earth and making it rotate the opposite direction. Let me stress, your car is NOT MOVING!! Therefore, it would help if everyone in their cars would travel together and go the same direction. If your chase teams will push the earth in the same direction, you'll all rotate the earth in the same direction more quickly and get the earth rotated into the proper alignment with the balloon more efficiently. Therefore, it is imperative that we prevent chase crews from leaving their homes from the opposite direction, as this pushes the earth in another direction at the same time. When one big and heavy chase truck tries to push the earth to the west, the rest of our lighter cars trying to push the earth to the east suffer. I for one do not want to see my gas mileage decrease because of this. So please be polite to everyone else and follow along with the rest of the pack.

This also highlights the importance of using the balloon launch announcements system. There are some weekends with multiple balloon launches. If they are occurring at the same time, our cars are fighting each other to rotate the earth to our proper positions. So be considerate and coordinate your launches with other teams across the country.

Just doing my part to clear things up,
Paul
(Next time I'll explain the relativistic effects of a balloon launch and why the Twin Paradox makes use younger after each balloon flight)

So if everyone drove their cars to the west or east all at the same time we could in effect speed up or slow down time by rotating the earth faster or slower! I think you've solved the "time machine" mystery! :)

>snip< ... If your chase teams will push the earth in the same direction, you'll all rotate the earth in the same direction more quickly and get the earth rotated into the proper alignment with the balloon more efficiently...<snip>

That explains the lighter, elated feeling I notice every time we
launched a balloon and the heavy feeling I get when the balloon
popped. The former was due tot he earth falling away from the balloon,
but I thought the latter was due to the electronics failure and
knowing we probably would not find the payloads!!! It was actually due
to the earth's acceleration towards the balloon! I feel so much better
now!

I enjoyed the write up! You should have saved it for April 1!

Seems once upon a time, NASA had a scheme to mount large rocket boosters
to the earth so that we could get rid of those pesky 'leap-seconds'...

Maybe if we are no longer gonna lead the world in human-rated space flight,
we should make good use of all those large and dangerous rocket motors ..!..

6482. PICAXE communication

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-21 00:04:56 UTC
From: L. Paul Verhage
Topic: 6482 Message: 6482

Has anyone tried sending a byte of data to a PICAXE using theterminal program?

I can display text sent to the terminal program with the SEROUT command. But I can't type a character into the terminal's buffer and send it to the PICAXE. The PICAXE acts like nothing was sent to it and it just waits. I don't see any documentation in the editor program about this and it has me stumped.

Does your terminal program require CTS and/or MR signals HIGH before xmitting?

Great perspective, Paul. Yup, I guess everything is relative.

Reminded me of a few years back when I was teaching theater lighting students about some of the finer points of illumination. There was this theory going around that light was actually everywhere but darkness was covering it up. All one had to do was remove the darkness to get light. Hence, light bulbs and lighting instruments were actually "Dark Suckers". If one could remove the "Darkness" we are left with light. Depending on how much of the "Darkness" in removed determines how bright an object becomes to our eyes. Fluorescent bulbs are about four times more efficient than incandescent ones at sucking up darkness.

Funny you should mention that.....

I wanted to clear up a misconception about why near space is dark......
(Not really, but it sounds good).

Although, if you're looking at pigments, black is all colors combined versus
in illumination where black is an absence of light. So I guess you could
say that in pigments, you need color suckers to get a color other than
black.

In that light, I feel compelled to warn this august community about
an emerging new threat to illumination: the dreaded Dark Emitting Diode
(DED).

These devices naturally evolve from silicon-based creations which
have been exposed to high temperatures, and have been proliferating in
our environment for over 50 years. Research has shown that a substance
known in the profession as MS (magic smoke) seems to suppress DED development,
which is statistically correlated (r < 0.1) by the release of noxious MS into
the atmosphere.

Unaccountably, DED development also appears to suppress the intended
functionality of the silicon devices from which they evolved, resulting
in the thoughtless disposal of said devices along with entire apparati
which they occupied. The only shred of light in this alarming story is
that DEDs and their accompanying baggage are frequently exported to nations
which may be suffering from an excess of illumination, thus helping
counterbalance US's unfavorable trade balance.

Forewarned is forearmed, patriots! Join me in supporting the Coalition
for Removal, Obliteration and Withdrawal of Dark Emitting Devices
(CROWDED), a 503c1 organization.

Well, CRUSH them before they propagate! And you should also know that
they can also lurk inside many other silicon deviceforms - some of which
can have 24 or more legs!

6489. A couple of HABing Questions

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-22 21:33:13 UTC
From: Pete Lilja
Topic: 6489 Message: 6489

I have in my mind that we're not supposed to release < 6 lb. payload untethered balloons within 5 miles of an airport without FAA permission / approval / waiver. Is that correct?

And this question is a bit silly but I'm going to ask anyway. Another of my many hobbies is flying high powered rockets. At a few launches I've placed in my larger rockets bottles of Crown Royal Whisky to enjoy later with my fellow rocketeers after the range has closed for the day. I've lofted full liter-sized glass bottles to the small, plastic airplane style bottles of the fine spirit without a negative outcome. As you've probably guessed by now I've been thinking of doing the same in a HAB. Since the highest altitude acheived for one of these High Spirit rocket flights has been just over 11,000' I am wondering what the opinion is amongst you more scientific-minded folks regarding the survivability of a small, plastic bottle of whisky would be at 100,000'? It could be sealed in a Ziplock bag or two just in case but I'm really wondering how well the bottle would take the extremes of a near space flight...I think it'd be fun to share a toast to HABing with some Space Whisky.

Lightweight, keep the whole thing under the 6 pounds and legally, I
guess not a problem// Ziplock bag forget it. and hard to say about the
regular small
bottle.it will have about 15 Psi inside it at altitude.

Joe WB9SBD Near Space Sciences
20+ years of HAB and counting.
47 launched & 47 recovered, 100% recovery!

If your payload is fully exempt per FAR-101.1, then the only other provisions that apply are 101.7, hazardous operations, i.e., dropping stuff on people or their property.

However, if your flight could get crossways with civil aviation, then it's a good idea to let the FAA know what you're up to, lest you get pilloried for negligence in the unlikely event of Gawd Forbid. Posting a HiBal and getting a NOTAM listed generally takes care of that and goes beyond your legal obligations per FAR-101 for exempt flights.

Re StratoBooze: If the plastic bottle's well capped and doesn't contain much air, then I'd think it could survive a flight. But you might wanna start out with just a shooter. Not sure what the freezing point of 80 proof Jack might be, but it'll likely be nice and chilled if you make a snappy recovery.

Just be sure you've got a designated T-totler driver for the trip back home from the recovery site :=}.

Kansas Wesleyan University physics club will launch this Saturday at 8 am from Salina KS EM18. We are expecting a SE track at this time.

Payload consists of APRS on 144.34 with 10 second updates (NØOY-11) and video on 439.250 Mhz (cable ch. 60) horizontal polarization with 2 watts output. Using a 1500 gr. balloon with He.

Wishing all success on receiving video and we will be interested in any reports.

6498. w3Baltrak site down

Yahoo group: GPSL (2009 — 2010)
Date: 2010-02-25 17:56:47 UTC
From: Keith Kaiser
Topic: 6498 Message: 6498

The prediction site is down due to an issue at the NOAA web site. It's been down all day and unfortunately we have no idea when it will be back up.

Sorry for any inconvenience this causes our users.

You can keep an eye on the NOAA site but check here; http://www.arl.noaa.gov/READYcmet.php and suppling a airport code and clicking on continue. Once their site is functioning again, ours will be too.

Pete, do you have any predictions as to where it might go?

I hope to either iGate or chase, but I'm down a radio so it will be one or the other.

Zack

I gating on 144.34 will be good.

Expect a southeast track from Salina,KS @ ~ 80-100 miles

Kansas Wesleyan University physics club will launch this Saturday at 8 am from Salina KS EM18. We are expecting a SE track at this time.

Payload consists of APRS on 144.34 with 10 second updates (NØOY-11) and video on 439.250 Mhz (cable ch. 60) horizontal polarization with 2 watts output. Using a 1500 gr. balloon

with He.

Wishing all success on receiving video and we will be interested in any reports.

Guys,

I recently received a note from Ivan Eremin (UA1CRX) at the Saint-Petersbur Balloon Experiment Group. They are in need of 1 to 3 balloons for some launches they want to do. But are unable to contact anyone here in the states to order them to from. Where are you guys ordering your balloons? I know some get them from eBay but other must be ordering through Kaymont or other sources.

Please let me know and I'll forward the info on to Ivan.

Thanks..

Hello Pete!

I am doing some testing for a MapPoint add-in I built. The add-in makes flight path predictions using READY data.
The track is southeast for Saturday morning and changes very little over a three hour period. The predicted landing is generally south of Wichita. I'd be happy to post or send a screen shot of the predicted paths.

Good luck with the flight!

I think Kaymont is the best bet, if they have stock of the size wanted.
Anytime I've ordered from them they have 1200g or 1500g in stock. I'll
probably find out tomorrow as I need to make my 2010 order soon.

Another possibility is Scientific Sales. Their balloons are more expensive
but the two 1500g balloons I got from them performed very well.

From: pete sias
Topic: 6505 Message: 6505

Has anyone re-used a 1200g Totex (Kaymont) balloon?

For example, use the balloon on a tether for testing then remove the He, store it for a week then re-inflate for the actual flight.

I left this balloon in Peru for the university to test their nano satellite package. They don't have the option of cheaply getting another balloon quickly, thus the question..

tnx Pete NØOY

Keith,

It appears NOAA ARL has reorganized their web site and perhaps has
permanently moved that functionality. I can't get a response through the
gus.arlhq.noaa.gov interface, though the page is still up. However, all
data including forecast wind profiles are accessible through the
www.arl.noaa.gov interface you list below.

Can the online utility be modified to use the new NOAA interface?

Yes...I've done this a couple of times....the most recent one was a balloon left on the ceiling of the balloon highbay here (after it escaped from the filling hose)....it sat there 3 weeks on the ceiling and we flew it after getting it down with a pole. Unfortunately, we didn't see the 1/8" hole in the balloon made by the rough ceiling....amazingly it didn't burst on inflation and made it up to about 28,000 feet before coming slowly back down intact....it actually took some effort to pop it once we pulled it down from the tree it was laying up against. That and the fact that you've had some amazing floater flights inspired me to try to intentionally put a continuous leak hole in the balloon nozzle (with PVC pipe fitting). I've done several floater flights using just an 1/16" hole that floated all night long over 100,000 feet and the folks in the UK have been doing the same thing successfully as well.

Hi Pete,

I guess it depends a lot on how much sunlight exposure it's received. UV
total dose is the most significant degradation factor for latex/neoprene.
If it's not discolored, then it may be nearly good as new - but I can't
say that from direct experience.

Just stumbled across this at Sparkfun : http :// www . sparkfun .com/commerce/ product_info . php ? products_id =9689

It's an air quality sensor by Sharp designed to detect dust and smoke; it looks like it would be fairly easy to integrate into most payloads, and could provide some interesting data, especially if historical data could be archived. Forest fire smoke plume detection and characterization strikes me as an obvious application... the link to the datasheet is on the Sparkfun page; any other ideas?

Let me look at the link, but one thing to look at is how dust free is the stratosphere. Big volcanic eruptions, meteor impacts, and nuclear war can drive dust into the stratosphere that can effect weather for years (since there's no rain to wash it out).

One thing to look at is how the lower air pressure effects its readings.

Very true; the application could be two-fold: a long-term observation of the statosphere (can we see a spike after a major eruption?), an shorter-term observations on the trip up. The biggest limitation that I saw was the rated temp. range... only spec'd down to -10C.

I just looked over the specs. It produces a voltage that can be read my the ADCs we typically use. It has a small hole for dust to flow through. We would need a fan on that to draw air. I also imagine you would want a funnel to concentrate the air.

Otherwise?

Hi Guys,

While Norm Kjome was at U Wyo, he flew monthly particulate sensors
for NCAR for several years. The sensors used a strobe light and
two separate photodetectors fitted with Fresnel lenses and optical
bandpass filters to differentiate particulate sizes based on backscatter.
The light path was mostly in the air outside the payload housing.
Obviously, these were night flights to avoid solar flux noise and
detector saturation.

Maybe Norm could pass on some of interesting results that his flights
brought back.

The spec sheet for the Sharp GP2Y1010AU0F sensor does show that it
uses an IR LED, probably with 850 or 1300 nm emission, so that's how
it can distinguish smoke from the larger dust. And yes, it's max
temp range is -10 - +65C, and it's also sensitive to ambient light
and condensation - further, the performance is just speced at 25C,
with a pretty broad zero and sensitivity range.

Might be fun to fly, and it's cheap enough, but I expect that one could
do about as well just looking at the sky :=).

6523. w3BalTrak back online

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-13 18:27:24 UTC
From: Keith Kaiser
Topic: 6523 Message: 6523

Troy has gotten the NSV w3BalTrak prediction page back online.
http://nearspaceventures.com/w3Baltrak/readyget.pl

He asks that someone run a bunch of plots as we're not sure what changes NOAA made to the forecaster.

On the first page, NOAA changed the GFS models from 3 to 2 so there's only 2 buttons, but everything else works the same. On the second page, the pulldown for "date/time nearest your launch date" will look different, but it's generated by NOAA. The difference appears to be be that it starts with the last forecast cycle and it used to start at an arbitrary, fixed time before.

Please give it a try everyone and let me know if you run into something that doesn't look right.

Thanks Troy for doing this for us, the entire ARHAB community says thank you.

Troy and Keith,

The online version appears to be working. I've made several runs since Saturday.

One minor typo, the 3hr GFS is available from 0 to 180 hours (not 84 as shown on the interface panel).

Thanks,
Howard

From: Mark Caviezel
Topic: 6529 Message: 6529

Paul:
Huntsville does indeed have a great rocket museum. There is a Saturn 5 on horizontal static display, a Saturn 5 mockup on vertical display, an H1 engine, a sectioned RL-10 engine, a composite fiber wrapped tank from Skylab that survived the re-entry flight, an SSME, a Centaur G-prime upperstage and my personal favorite, one of the 'balloon tank' Atlas rockets, I think it is an Atlas G, on static display. The Atlas G leaks a little bit and there is an old air compressor that kicks on periodically to keep it pressurized with air.

I find it interesting that the stainless steel balloon tank Atlas has been replaced in modern rockets with lower performance isogrid aluminum propellant tanks.

best

6530. BalTrak Troubles?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-16 00:06:48 UTC
From: Pete Lilja
Topic: 6530 Message: 6530

I've been trying to run some flight sims for a HAB we have planned for this Thursday and have been getting widely crazy results.

I dunno if I can attach files to this email showing screen shots but I am launching from NE Iowa at 42.7137, 092.6347 with a 1200 fpm ascent and descent with a starting elevation of 900 feet and using ALO as the Wx station. for the date of 2010-03-18 at 08:00:00 hours. Burst altitude 95,000'.

The predicted flight path ascends SE (as expected) then darts in a *straight * line *NW* at about 70,000' (best guess) until and ends with a normal looking final descent. It is really weird. I've never seen this before and am wondering what's up.

Below is the pasted data for the sim if that helps.

Thanks

Pete

6532. Re: [Balloon_Sked] BalTrak Troubles?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-16 01:04:45 UTC
From: BASE
Topic: 6530 Message: 6532

Dear Pete and James,

I am seeing the same thing on our Thursday predictions for a flight in Indiana. Flight at 15 UTC on 18 Mar has SW reversal and 18 UTC and 21 UTC show the northwest jag that you describe. As James just said, it is that last data line that is causing the dart and it is in the GFS models.

Run the Cambridge model with 5 m/s ascent (1000 ft/min)

http://www.srcf.ucam.org/~cuspaceflight/ predict/ index.php

and you'll see the difference.

I have encountered similar flight paths in mid-summer and had one flight like this in April 2008.

Personally, the difference in the landing location can put me into very heavily forested areas in southern Indiana. I still don't see any evidence of this reverse jet in the actual sounding balloon data (at least as of 12 Z today from ILX).

Tomorrow will be an interesting day to watch both the models and the winds.

Howard

I've been trying to run some flight sims for a HAB we have planned for this Thursday and have been getting widely crazy results.

I dunno if I can attach files to this email showing screen shots but I am launching from NE Iowa at 42.7137, 092.6347 with a 1200 fpm ascent and descent with a starting elevation of 900 feet and using ALO as the Wx station. for the date of 2010-03-18 at 08:00:00 hours. Burst altitude 95,000'.

The predicted flight path ascends SE (as expected) then darts in a straight line NW at about 70,000' (best guess) until and ends with a normal looking final descent. It is really weird. I've never seen this before and am wondering what's up.

Below is the pasted data for the sim if that helps.

Thanks

Pete

Hello Pete!

I am developing an add-in for MapPoint which predicts, reviews, and tracks balloon flights. I entered your information and the add-in provided the attached information. The Prediction function creates three flight paths at different ascent rates using the READY data. It creates three more flight paths (also at different ascent rates) using the READY data and up to your estimated burst of 95,000.

I didn't see anything odd however I may be using a newer set of data. I have seen predictions with the path you saw and the flight followed the predicted path. The high altitude wind seems to go in a different direction.

Take a look and let me know what you think! I expect my add-in will be ready near the end of the month.

I just ran a prediction using SWO GFS 0600 hrs for a flight from Stillwater, Ok and I don't see any annomalies with the flight prediction up to 100k.

I have been seeing oddities as well at high altitudes. I think something is using wrong wind information above the 20mb level when doing a full cut-and-paste per the directions.

Note that Pete's highest wind value (20mb, about 85,000 ft) is from the NW (314 deg) at 6 m/s. That should push the track towards the southeast at a relatively slow pace above 85,000 ft. Instead, it's going towards the northeast at a high rate of speed.

There is nothing in the wind forecast from NOAA that should cause a jog in the track like this.

So far, I have been able to mitigate this by pasting only down to the 20mb line, ignoring all text including and after 'hysplit." blah blah blah. Don't know yet if that's a 100% fix.

This morning I ran the NSV online program as directed, copying the entire file and received a bad track for the flight above 26 km.?

When I only submitted the data up to and including the combined data table, as Mark suggested, I saw the expected flight path (which is also seen on the Cambridge U Spaceflight Landing prediction).

That's the good news. The bad news for me is the anticipated landing site, with a campus launch, is in the Morgan-Monroe State Forest.? If I can't work around the flight path, I may need to have Harry come up from Oklahoma and help with a tree recovery!

Looks like we may need to go on the road for our launch.?

6538. Supersonic jump from balloon planned

Yahoo group: GPSL (2009 — 2010)

From: Mark Conner
Topic: 6538 Message: 6538

New York Times
March 16, 2010
Pg. D1

Findings

A Supersonic Jump, From 23 Miles In The Air

By John Tierney

Ordinarily, Felix Baumgartner would not need a lot of practice in the science of falling.

He has jumped off two of the tallest buildings in the world, as well as the statue of Christ in Rio de Janeiro (a 95-foot leap for which he claimed a low-altitude record for parachuting). He has sky-dived across the English Channel. He once plunged into the black void of a 623-foot-deep cave, which he formerly considered the most difficult jump of his career.

But now Fearless Felix, as his fans call him, has something more difficult on the agenda: jumping from a helium balloon in the stratosphere at least 120,000 feet above Earth. Within about half a minute, he figures, he would be going 690 miles per hour and become the first skydiver to break the speed of sound. After a free fall lasting five and a half minutes, his parachute would open and land him about 23 miles below the balloon.

At least, that's the plan, although no one really knows what the shock wave will do to his body as it exceeds the speed of sound. The jump, expected sometime this year, would break one of the most venerable aerospace records. For half a century, no one has surpassed (one person died trying) the altitude record set by Joe Kittinger as part of an Air Force program called Project Excelsior.

In 1960, Mr. Kittinger, then a 32-year-old Air Force pilot, jumped from a balloon 102,800 feet above the New Mexico desert. Today, at 81, Mr. Kittinger is a retired colonel and part of the Red Bull Stratos team working on Mr. Baumgartner's jump, which is being financed by the energy-drink company.

"For 50 years," Mr. Kittinger said, "I've gotten phone calls from all over the world, people wanting to break my record — one a month, sometimes two a month. But I stayed away from them because they didn't have any idea what the challenge was. What attracted me to Red Bull was their methodological approach to safety and to providing scientific benefits."

More than three dozen veterans of NASA, the Air Force and the aerospace industry have been working for three years to plan the jump, build a balloon

and pressurized capsule, and customize an astronaut’s suit for Mr. Baumgartner. Besides aiming at records, they’re doing physiological research and developing procedures for future astronauts to survive a loss of cabin pressure or an emergency bailout in the stratosphere.

One of the chief concerns has been to avoid the problem that almost killed Mr. Kittinger during Project Excelsior. He was supposed to be stabilized during his fall by a small drogue parachute, but on one training jump in 1959 it did not open because the cord got tangled around his neck.

As a result, Mr. Kittinger’s body went into a spin that reached 120 revolutions per minute as he plummeted more than 60,000 feet. He blacked out and regained consciousness only after his reserve parachute opened automatically about a mile above the ground. When he came to, he later wrote, he first assumed he must have died, but then he spotted the parachute’s canopy above him and made a sudden realization: “I am impossibly, wonderfully *alive*.”

Mr. Baumgartner hopes to remain stable and conscious throughout his longer fall without relying on a drogue parachute. He plans to avoid spinning by adjusting the angle of his body and keeping his arms at his side.

This stabilizing technique would ordinarily be fairly easy for an expert like Mr. Baumgartner, 41, a former paratrooper in the Austrian Special Forces and a veteran of more than 2,500 jumps from planes, cliffs and assorted landmarks. But to survive the stratosphere’s near vacuum and frigid temperatures, he will need a sealed helmet and a pressurized suit.

Would he be able to do midair maneuvers in such a bulky contraption? To find out, Mr. Baumgartner and his team recently went to a wind tunnel in Perris, Calif., near Los Angeles, and put the suit through its paces.

Team members suited up Mr. Baumgartner, turned on the oxygen in his helmet and attached a pack to his chest containing equipment to record his vital signs, track his position using GPS satellites and heat his helmet’s visor to keep it from fogging.

By the time the suit was inflated to its full pressure of three pounds per square inch, he looked like a robotic version of the Incredible Hulk. As he walked stiffly into the wind tunnel, it was easy to see why astronauts lack a certain grace.

But once Mr. Baumgartner was inside, held aloft by air blowing upward at 130 miles per hour, he looked comfortable enough, much to the relief of the engineers. By adjusting his arms and legs, he could shoot up in the tunnel or bring himself down. Most important, with his body angled at 45 degrees to the ground, he could maintain the desired arrowlike stance: head first, arms and legs pointing backward in a V shape called the delta position.

“It was difficult, but it worked,” Mr. Baumgartner said after emerging from the tunnel. “Now I’m confident I can handle the suit in regular free fall as long as we’re not breaking the speed of sound. But as soon as it goes from

subsonic to transonic to supersonic, we don’t know what to expect.”

Plenty of planes have broken the sound barrier, but transonic humans are a mystery, said Art Thompson, the technical project director for the Red Bull Stratos mission, and a former Northrop engineer who worked on the B-2 stealth bomber.

“You can run a lot of models, but with the human body you’re not dealing with a hard surface or a ballistic shape,” Mr. Thompson said. “You’ve got this rounded bulbous helmet, and the shoulders and the feet sticking out, and everything starts to happen at different times. Parts of your body may be going supersonic while others aren’t, causing flutter waves pulling back and forth among the surfaces.”

Could such waves harm the body? Could they create disastrous turbulence?

“We just don’t know what will happen to Felix and the suit when he goes supersonic,” said another Stratos engineer, Mike Todd, who worked on high-altitude suits for the Air Force’s spy-plane pilots with the renowned Skunk Works research division of Lockheed. “Felix could slip right through it, but if half the suit’s supersonic and the other half isn’t, there could be turbulence that knocks him out of control.”

Such risks are one reason why Mr. Kittinger’s record has stood for half a century. Air Force and NASA officials have become understandably reluctant to explain potential mishaps to Congressional committees. (To debate the risks and benefits of this project, go to nytimes.com/tierneylab.)

But private adventurers have more freedom to take their own risks. The Stratos medical director, Dr. Jonathan Clark, who formerly oversaw the health of space shuttle crews at NASA, says that the spirit of this project reminds him of stories from the first days of the space age.

“This is really risky stuff, putting someone up there in that extreme environment and breaking the sound barrier,” Dr. Clark said. “It’s going to be a major technical feat. It’s like early NASA, this heady feeling that we don’t know what we’re up against but we’re going to do everything we can to overcome it.”

Thanks for all of the input on this.

I reran the sim removing the text below the 'hysplit' and have a more believable flight path. It is, however, quite a bit different than the path predicted by Cambridge U's simulator. Both look plausible in their direction of flight so I'm not sure which to 'believe.'

I'll keep playing around and see what happens through today and tomorrow regarding these sims. The bottom line is this is all fun and that's why I do it.

There may be differences in horizontal, vertical, and time interpolation of the wind fields being done by the two programs which could affect how to project the balloon's flight. Cambridge might also be using one of the UK Met Office weather models for their wind fields too - that will definitely lead to differences in the track.

6542. Mini Video Camera

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-16 17:31:32 UTC
From: mw@omsrc.com
Topic: 6530 Message: 6542

Hi All,

Around Christmas, I purchased a MUVI brand 640x480 full frame rate mini video camera for our ARBONET flights. It has a strong metal body made for recreational videos, such as skiing or mountain biking. Today came across even a smaller mini video cam for $40.00 less targeting RC cars and aircraft.

Amazing that you can get 4-6 hours of video from such a small, low-weight device at $60.00... The resolution is 640 x 480 so it is not HD, but previous ARBONET flights with 640 x 480 with a fairly large, low frame rate DV cam looked reasonable and lets you capture some of the story about the flight in fair detail.

See the links below:

At Hobbypartz:

Hi Michael

We're planning on flying two similar cameras on our first flight in May. Both were purchased from eBay as "spy" cameras. One is this style (aka chewing gum) and the other is often referred to as a Mini-DV or MD80. Our old 10 frame/sec cameras from gave us video that was good enough to make you lose your lunch after a few minutes of watching. We're hoping that these will be even better. ;-)

If we can do our flight on the 27th, I'll have a report on the Kodak Zi6's performance. They have been discounted at Office Max for the last 2-3 weeks to about $70-80. The camera can shoot WVGA, 720p/30fps, and 720p/60fps and uses 2 AA lithium batteries - tests so far indicate they'll last plenty long for a typical two-hour mission. Not as small as the chewing-gum-pack cameras but small enough to go on most any payload.

I know what you mean! On our last flight the Richardson Wireless Club's payload departed the flight prematurely when their antenna wire broke on the ride down. I looked at the video in detail while it was wildly headed earthbound to see if we could pin a time and maybe see a feature on the land below to help locate it. I was about one hiccup from needing Dramamine after the hour + I took to view and find the break point! :)

From: L. Paul Verhage
Topic: 6546 Message: 6546

That's on the sign outside the patio door where I'm staying for training. Last night there was an alligator in the pond next to the patio. At first it was sunning itself. Later it swam around the pond and stopped about 30 feet away to watch me as I watched it.

Funny that it said, "psst, come here".

6547. BASE 41 - 18 March

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-17 15:23:15 UTC
From: BASE
Topic: 6547 Message: 6547

Dear friends,

After running several predictions, both with GFS and NAM models and actual upper level soundings, BASE announces that we fly tomorrow. Launch will occur as close to 1700 UTC (1 pm Eastern Daylight time) as possible.

Launch site will be from the western end of the North Montgomery School property north of Crawfordsville, Indiana. Primary payload is a set of energy discriminating geiger counters. We will also fly tilt axis sensors and video cameras. Secondary position information via APRS on 144.39 MHz every two minutes using the WIDE2,1 path.

This flight has strong GPSL flavor. The primary balloon is a 1000 gram latex acquired from Zach Clobes. In an effort to avoid trees and populated areas, we will follow the sage wisdom of Mike Manes and "give it a little more gas." Descent will be on a smaller parachute.

Surface winds at launch will be at or above 10 miles per hour. The flight should be short, both in time and distance. Predicted landing after 90 to 100 minutes near North Salem, Indiana.

Thanks for your support,
Howard

6548. Re: [GPSL] BalTrak Troubles?

I'm going to do some more test runs tonight and compare them to Balloon Track on my PC....the initial testing I did last weekend showed that the CU prediction site (although the right path and direction) tended to be about 10 to 20 percent too far in landing spot prediction as if the ascent rate was slower, and yes, I'm converting from ft/min to m/s. The online Balloon Track above about 85,000 feet showed a fast westerly path for the top end of the flight path and as a consequence was way off....calculating a peak altitude below about 85,000 feet gave accurate paths. I'll try Mark's fix by leaving off the text after the 20 mbar level and see if that works.

Thanks for all of the input on this.

I reran the sim removing the text below the 'hysplit' and have a more believable flight path. It is, however, quite a bit different than the path predicted by Cambridge U's simulator. Both look plausible in their direction of flight so I'm not sure which to 'believe.'

I'll keep playing around and see what happens through today and tomorrow regarding these sims. The bottom line is this is all fun and that's why I do it.

I have been seeing oddities as well at high altitudes. I think something is using wrong wind information above the 20mb level when doing a full cut-and-paste per the directions.

Note that Pete's highest wind value (20mb, about 85,000 ft) is from the NW (314 deg) at 6 m/s. That should push the track towards the southeast at a relatively slow pace above 85,000 ft. Instead, it's going towards the northeast at a high rate of speed.

There is nothing in the wind forecast from NOAA that should cause a jog in the track like this.

So far, I have been able to mitigate this by pasting only down to the 20mb line, ignoring all text including and after 'hysplit." blah blah blah. Don't know yet if that's a 100% fix.

Mark's fix is working fine for me on the Near Space Ventures online predictor.

I also agree with Bill's assessment of the two programs. The prediction for 1500 ft/min ascent (7.62 m/s) and 1200 ft/min (6.09 m/a) on the Cambridge system lands about one mile from 1200 ft/min ascent and descent rate on the NSV online site.

6550. Balloon Tracking program comparison test results

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-18 04:07:55 UTC
From: wb8elk@aol.com
Topic: 6550 Message: 6550

I ran the prediction for this Saturday for my location on the following programs: Online Balloon Track, CU Spaceflight and compared them against my PC based Balloon Track program.

All three are aligned during the ascent stage and match the burst point.....the difference seems to be the way that CU Spaceflight models the parachute descent as their model puts the payload about 8 miles farther downrange than Balloon Track. My comparison test parameters were for 1000 ft/min ascent (5.08 m/s) and 1300 ft/min descent (6.6 m/s) and 102,000 burst altitude. NOTE: to use the CU program, you need to convert ft/min to m/s by multiplying by 0.00508....conversely converting from m/s to ft/min you multiply by 196.85.

However, online Balloon Track will give you an error by putting in a fast westerly track if you run your prediction over the 20 mbar altitude (about 86,000 feet). I would guess that the problem lies with the change NOAA READY has made to their text data output....the difference is that just after the 20 mbar wind data the old data file would say GFSFLL...the new one says hysplit (shown below). There are also a few differences in text at the very end of the file.

The quick fix that seems to work for online Balloon Track is Mark's suggestion to cut and past the wind data only to the 20 mbar point at the first portion of the data file and leave the rest out. The PC version of Balloon Track will work with the full file with no problems.

Old NOAA data format:

150. 13943. -58.6 -77.6 270.0 28.4
100. 16461. -61.9 -273.1 255.9 14.3
50. 20784. -57.4 -273.1 168.5 3.4
20. 26758. -44.1 -273.1 96.1 7.0

GFSFLL
Lat/Lon/Elev: 39.27 -85.90 200m
E = Estimated Surface Height

========Mean Sea Level Pressure=====

6553. BASE 41 - successfully completed

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-18 21:50:40 UTC
From: BASE
Topic: 6553 Message: 6553

Dear friends,

BASE 41 went up came down and we brought everything home. Less than five hours and 125 miles on the vehicle for the entire trip.

Only two significant problems.

One - the 144.39 MHz APRS radio had developed some battery problem that was not noticed during the reprogramming and recharge earlier this week. The emergency battery pack that was quickly spliced into the power input failed at a connector to one of the batteries (evidentally at about 25 kft ASL).

Two - the initially filled 1000 gram Kaysam balloon tore apart at the top of the spreader ring just before we tied it off. The steady winds had driven the balloon into a fascinating oscillation pattern. One of my students caught the balloon with his hand, but there was no neck left to tie off. That balloon did serve as a good indicator of the initial launch direction, but we already knew that with the 10+ mile/hour surface winds. A 1200 gram Kaymont was fitted to the flight string and the flight went off after the additional twenty minute delay.

Burst was just under 90 kft ASL and the landing was witnessed by the launch team and a set of construction workers. The foreman retrieved the payloads before I secured permission to enter.

Additional details will be posted. All experiments appeared to work. Now the data analysis begins.

From: BASE
Topic: 6554 Message: 6554

I have committed to flying ATV at Space Jam 4 for the Boy Scouts in Rantoul, Illinois on August 7. Although I have a nice transmitter, I know that I will not have the time to build, and test fly an ATV system before the August date. I do not want to disappoint the Scouts.

Would anyone be willing to fly an ATV system at the GPSL and then let me borrow it for the Scout flight two weeks later? If I could see ATV via balloon in operation, I would have more confidence in the system and my ability to get it to work.

Alternatively, if someone with ATV experience wants to come to Rantoul on the first weekend in August, I know that we'd be able to help you have a great time. The amateur operators in the area were great help during last year's event.

Thanks in advance,
Howard

I know a couple of us are using Twitter. I read that since Twitter doesn't allow you to categorize your tweets, people are using hashtags. I checked Twitter and it's not being used, so I propose we use the #ARHAB hashtag.

If you will end your tweets with #ARHAB, people can search #ARHAB and find all messages that incorporate that hashtag. That would allow anyone to find any tweet referencing near space.

For GPSL, I recommend anyone tweeting about the conference to use both #ARHAB and #GPSL.

Topic: 6558 Message: 6561

FYI - Just a few thoughts on Twitter, Facebook & MySpace from the IT guys in our car club.

"Twitter collects your personal information and shares it with advertisers that can then target users via their history of tweets! Sometimes yout tweets may even show up in advertisements. SMS spoofing is far more difficult than cut and paste coding of virus and exploit files, SO TWITTER ALL YA' WANT but hope that the site administrators have their %#@! together."

"Over 500,000 PRIVATE MySpace users photos have been downloaded from MySpace using a bug published on YouTube back in 2008. If I remember correctly it was released by the Piratebay and available on most of the torrent sites that so many of us (geeks) have used for years! Social-networking sites like MySpace are turning out to be festering nests for spyware, some bulletins show up like an advertisement that provides a link to a fake login screen, tricking people into entering their MySpace e-mail and password... Bam, you've been phished!
BASE64 encoding (used a lot on my space links and bulletins) has inherent flaws that some of us (geeks) are able to exploit...Sort of like the XHTML,Opera and javascript that run behind the scenes on this website."

dont forget the volunerability that was posted about both myspace and facebook, Chross Site XML Scripting, for reasons like this some websites such as deviant art, FA and a few others have disabled a few features untill this can be patched, but that does kinda fall into the "download first" media that MS uses and that a few other web pages use so that the special features (videos, flash, audio, etc) can be played without having to constantly refresh and stream the media to the users machine, alost of this i've run into while doing some security scans for a few friends of mine on MS (i'm working on getting my C|EH) all i've got to say is be careful what you post, and if possable dont use the myspace media if it requires download to view

Facebook can be managed with some common sense practices. An example is not to enter a full birthday just month and day (or not at all). You can set your settings to ignore the Facebook games (recommended) and causes and only accept as friends you can verify. If someone is filling it with stuff you do not want to see you can un-friend them. It may have a positive benefit in that you can have others follow along with the effort. Just keep it business like and there should be no issues. We had a sign up here at work about 8 months ago and other than making a few minor changes to my profile it has been somewhat decent.

It is far from perfect and it has gone through some changes but I find it workable as it has more flexibility than just tweeting.

Harry

What dirt do you have on Facebook? Would it be the lesser of evils?

Subject: Re: [GPSL] ARHAB Hashtag

FYI - Just a few thoughts on Twitter, Facebook & MySpace from the
IT guys in our car club.

"Twitter collects your personal information and shares it
with advertisers that can then target users via their history of tweets!
Sometimes yout tweets may even show up in advertisements. SMS spoofing is
far more difficult than cut and paste coding of virus and exploit files, SO
TWITTER ALL YA' WANT but hope that the site administrators have their %#@!
together."

"Over 500,000 PRIVATE MySpace users photos have been
downloaded from MySpace using a bug published on YouTube back in 2008. If I
remember correctly it was released by the Piratebay and available on most of the
torrent sites that so many of us (geeks) have used for years!
Social-networking sites like
MySpace are turning out to be festering nests for spyware, some bulletins show
up like an advertisement that provides a link to a fake login screen, tricking
people into entering their MySpace e-mail and password... Bam, you've been
phished!
BASE64 encoding (used a lot on my space links and bulletins) has
inherent flaws that some of us (geeks) are able to exploit...Sort of like the
XHTML,Opera and javascript that run behind the scenes on this
website."

dont
forget the volunerability that was posted about both myspace and facebook,
Chross Site XML Scripting, for reasons like this some websites such as deviant
art, FA and a few others have disabled a few features untill this can be
patched, but that does kinda fall into the "download first" media that MS uses
and that a few other web pages use so that the special features (videos, flash,
audio, etc) can be played without having to constantly refresh and stream the
media to the users machine, alost of this i've run into while doing some
security scans for a few friends of mine on MS (i'm working on getting my C|EH)

all i've got to say is be careful what you post, and if possable dont use the myspace media if it requires download to
view

Hey all,
In the UK we've started using twitter - its quite a good way to keep
people up to date with how the launch preparations are going and the
status of the flight and recovery. While the message character count
is low its a lot easier to use in the field rather then having to pull
up big data rich websites.

I agree with you that caution is the word, but even with that I've heard there is stuff going on in the background that I don't like.

I personally don't have any dirt. I'd have to talk to the IT guys. The problem is, I'm not that versed in this stuff and what they tell me will probly go right over my head. :)

I have a MySpace page only to post pics & videos. I get a lot of crap out of the blue even with that so I don't Twit or Face.

I have only been a Facebook user and not done any MySpace and have no Twitter experience except I have one friend who uses Twitter to post comments and he has them cross post over to Facebook.

My only experience with things that may not be right with Facebook is that I do have people post (though friend finder) requesting to be my friend. While this might seem innocent, I usually ignore them and only follow up if they have listed a mutual friend. I have been known to question the mutual friend about them before I request as well. Since I do not play the games I am not familiar with any evils that may lurk there. I also do not run any volunteer apps that may lurk as well. Again, just being logically caution minded as anyone would if they received something that would say "click here to see my pics" out of the blue. Facebook is more data intensive than Twitter but like sharing the photo aspects of it.

I would suggest that if some one wants to Tweet, maybe they could cross post into a GPSL link on Facebook. But if there any horror stories about any of these instant messengers I would like to hear more about their experiences.

I've had good experiences with Facebook, but not much experience with Twitter. At the risk of sounding like a luddite, are the hash tags strictly for the sake of searching? Do they have any other purpose?

Zack

6568. Re: [GPSL] ARHAB Hashtag

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-23 03:26:27 UTC
From: Greg Williams
Topic: 6558 Message: 6568

The hashtags can draw attention to a particular word or phrase. The word/phrase with the "#" will denote that the word/phrase is not part of the message's syntax, but is being used for search purposes. The "#" is not necessary if you are using the word/phrase in your "tweet".

Example, you're at GPSL and you want to post that a balloon reached 100,000 feet. If you want people who are looking specifically for GPSL messages to read You can send the following:

"Our balloon has just passed 100k feet altitude #gpsl"

This will alert those following any tweet featuring "GPSL" to your message. Other good hashtags might be #arhab, #ballooning, and the nickname of your payload.

You can also send the following without needing the "#" symbol:

"Just arrived at the hotel for tomorrow's GPSL gathering". Sometimes you can use the # for phrases, names, etc.

"Just arrived at the hotel for #GPSL tomorrow"

You can connect your Twitter to your Facebook page. So if you update Twitter, it will also update Facebook. It's pretty useful in a situation where, say you are mobile on a road trip, and you send a text msg via your cell phone to your Twitter account:

"Any good repeaters to use in Knoxville, TN?" or "Any good #repeaters to use in #knoxville, #tennessee? #hamr"

This way, hams on your twitter feed, facebook, and anyone who might search twitter for tweets featuring "Knoxville" and "Tennessee" or "hamr" even "repeaters" can possibly suggest good repeaters for you to listen to.

Hopefully your phone will have web browsing on Twitter/FB, or the person has your cell pnone # and can call or message you. If I'm stopped on a road trip for a meal break I try to find a restaurant with WiFi so I can use my laptop.

Sometimes the hashtags can be used to draw attention to other users. For example, on Fridays, many Twitter users will post other users on their list that you can follow (called "#FollowFriday", or "#FF"). This might help you locate other hams on Twitter, or folks in your area.

Hope this helps.

Another $.02 ... (YMMV)

As with any tool, the finished product is a function of the craftsman.
Any internet/computer application/environment can be used insecurely.
Stuff deserving of protection needs firewalls, and access controls, etc.
Twitter, FB or MySpace is not the right place for sensitive information.

FaceBook can be a useful place for a club to collect information, stories,
pictures to share, and present public information. I don't do much there.
With a teenage daughter, I needed to understand the security settings.
Don't assume the defaults are best, regularly review your privacy settings.
A lot of folks from my past-lives have found me as a result of being there.
Again - Your Mileage May Vary . . . That can be good, and that can be bad.

Twitter is like APRS short messaging for the internet. Very timely, wide
distribution - I find lots of good links. BUT, just like with email & web
- you HAVE TO consider the source, and be careful what you click....
I get lots of breaking news this way, I don't usually want the details.
In the ARES and EmComm environment, we find Twitter very quick & useful.

If you don't have current A-V and updated browsers, Ur screwed anyway.

With a handy Twitter Widget on my Wordpress blog,
I can quickly add an interesting link onto my home page... via Twitter.
Go see for yourself : http://wb5rmg.wordpress.com - right sidebar.

Thanks /;^)

Not sure if the blizzard that's raging as we speak here in the Denver area will lose some oomph before it gets to you, but it's the worst to hit us so far this winter. Started out w/ rain/snow mix at 1630, and now (1930) there's 6" of white on the pavement - although the 25 kt NW winds are making for a lot of drifting. And my son just called from the NW 'burbs to report that he'd lost power. The forecast if for it to pass sometime tomorrow afternoon, leaving a foot or more behind.

Like almost every article on hab in the mainstream media (including
any we've had) it's presented entirely without context and like no one
has ever done it before. There's no hope really :)

I have started an article on how several American balloons launched from the USA for Britain almost make it to Britain, yet the Brits don't have the technology to guide their balloons from Britain to the US, not a single one even leaving the British coast line for America! :)

I am happy for the Ham reaching this goal he set, but very bad, uninformed reporting burns me. Citing previous art by researching the story is reporting 101.

Plus it's all where you live also.

Being one of the originals, been doing these flights for over 20 years now. 48 flights with 100% recovery and close to that in success of the missions goals.

But here we are under the umbrella of the University of Wisconsin. Where if it has anything to do with Science or technology at all, if youre not the University doing it you don't know crap, and are totally ignored!

After fighting this mentality here in this state I have all but given up trying to get the press to cover the launches at all.

The U of W could fly a turd on a mylar party balloon to 200 feet, and it will be on the statewide newspapers front page. as being technology breaking news.

Oh well,,

6578. How often does the WX Station update the weather data?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-25 22:25:16 UTC
From: k6rpt
Topic: 6578 Message: 6578

How often does the WX Station update the weather data? I'm trying to pick a launch site that would put my flight down in central California farm land. Wednesday the flight predication was north to south and today it is west to east. The flight is scheduled for this Saturday, how early can I get a good flight predication?
Thanks,
-Ron K6RPT

Any of you as disgusted as I am!?

The guy in England sends a Canon Powershot aloft on a balloon and it
gets world wide acclaim for being the first to do this.

Is Amateur Radio soo antiquated that as soon as they hear the words Ham
Radio or Amateur radio they all think we are stone age technology?

Man, I get soo pissed MIT and their cell phone big freaking deal,
now this guy in england and his camera,

why is not any of the incredible missions we all do ever covered?

wow the media,

my wife and I just say NBC news

my non-ham wife said "isn't that basicly what you guys do?
they even have a picture with the guy posting with your kind of antenna."

wonder if St. Louis can get the same coverage in May.
Or all of us in July.

I wonder if this is to make the public think of NASA as extremely outdated, so the President can sharply cut thier budget?

Sincerely,
Carlton Corbitt

Yikes! That is a load.

Well, as I see, it the answer is to either ignore it or contact your local media and have them come along for a flight.

That is rather poor reporting, however.

Those are terrific images!

Yes ther are nice. But there are a dozen groups here in the USA that have just as many Nice pics as those. and are totally ignored.

if it's with a cell phone and crappy pictures it gets ton of world wide press.

If it's a geek that spends 800 bucks on his aprs system, wow he got ripped off! and attaches his camera to it, like wow huh?

Yet i know of at least 4 groups here in the states that have just as nice images, and even full color live motion video,,

but do we get any press?

Nope it's amateur radio ya know that old grandpa guy in his basement and his morese code ya know we can't or don't do neat stuff like this.

6583. Re: [GPSL] How often does the WX Station update the weather data?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-26 00:14:00 UTC
From: BASE
Topic: 6578 Message: 6583

Ron,

The future winds at READY models, which are used by the Near Space Ventures website are updated every six hours.

Whenever I use the wind predictions, I like to run models for 24 hours before anticipated launch through 24 hours after the launch time. Sometimes the dramatic swings are due to a passing weather front.

Since you are within 72 hours of launch, I would hope that the models will stop swinging wildly unless there is a pending weather event.

As long as we're talking about running the models, I also run a variety of ascent and descent speeds (500 ft/min to 1500 ft/min on way up, and 1000 to 1500 ft/min on the way down) with three different burst heights framing the predicted burst height from LiftWin.

Hope this helps,
Howard

Yes! Many nice photos all over. Our group has many hundreds of them ourselves (but we have none of the UK [?]).

After a flight last Fall I sent a photo to the local TV weather guy. They aired it and commented it was cool but that was about it.

I guess this doesn't bother me because we do it for the thrill and the fun of the challenge of HABbing.

Like everything in life, I guess, media hits are fickle and a matter of timing.

From: wb8elk@aol.com
Topic: 6578 Message: 6587

Hi Ron,

I get reasonably accurate predictions about 2 to 3 days from launch....in particular the 36 hour and 24 hour predictions are rather good and I find that the 18 hour in advance one (night before launch) is a good one....usually not a lot of change between that one and the morning predictions of the actual launch day unless there's an active weather front coming through.

So, my answer is that the night beforehand you'll have good data to work with and a good trend about 2 to 3 days beforehand.

- Bill WB8ELK

Ron if you email me your balloon size, payload weight and estimated launchsite, I'll run a prediction for you to see where you'd have to be to land in the central valley. I've flown in that area a number of times.

How often does the WX Station update the weather data? I'm trying to pick a launch site that would put my flight down in central California farm land. Wednesday the flight predication was north to south and today it is west to east. The flight is scheduled for this Saturday, how early can I get a good flight predication?
Thanks,
-Ron K6RPT

Hi Mark,

We think in similar ways...I just sent a comment to NBC News on that very link prior to reading your email with the link.

I do congratulate Robert Harrison on spreading the word about high altitude balloons to the world. I've been in touch with him and other balloon folks in the UK via email over the past year or two now and he does a nice job working on the modified FL-digi program as well as work on the SpaceNear.us balloon tracking program along with James Coxon. There are others in his balloon group that participate in the flights there from what I understand and there is also quite a nice balloon program at Cambridge. I would assume that he didn't intend the NBC reporter to make the statement saying he was the first to have ever flown a camera into Near Space (I emailed NBC's Mike Taibbi to correct him on that statement)...I know that many of you have flown that exact Canon Powershot camera for years now. The original report in the UK also stated he held the highest altitude record for weather balloons...that may be so in the UK but not the world as many of us have exceeded his highest flight.

You have to understand bigtime news media....the story showing that one person can "beat NASA" for pennies compared to billions plays well and is somewhat of a editorial formula to capture the public's attention. Basically the same story was written about the MIT students and the Spanish students before that, the headlines were almost the same wording....but as those stories are months old, they are long forgotten by the very short attention span of the public by now so the formula still works.

The balloon groups in the UK have to surmount very difficult barriers to fly there. They have to approve their flights weeks in advance and they are not allowed to use amateur radio since the byzantine laws from their version of the FCC prohibit amateur radio in airplanes and balloons. As a consequence, they have to rely on 10 milliwatt 434 MHz transmitters running 50 baud ASCII RTTY...which is a challenge to track down for even the most experienced of us. They can't use the existing APRS network which makes our lives a lot easier here in the US. Add to that the problem of being surrounded by water and the good possibility of landing in another country.

As to some of the posts I read earlier being upset about the report since many of us have been at this for decades with very little recognition....If your local media isn't interested (although you might want to hit them up now that the skillet is hot), then my advice is to reach out to the world and start up a Wiki for your group in addition to your website...and post some of your favorite photos and videos there. Sooner or later some reporter will decide to do fact checking while doing a report and see what other groups are doing. We live in a world where flashy websites get the most attention and Wiki sites have become the online Encyclopedias of today (whether they are accurate or not). The main exception to this is the elegantly plain website of Google. If you want the general public to notice your activities and accomplishments, start with a flashy website along with a Wiki... post your favorite videos on YouTube and consider doing ballooning Facebook and

Twitter sites. With these kind of tools, we now have an unprecedented ability to promote our achievements to the world right from our home computers. You might want to find someone in your group who is a web guru since keeping up with all this will take a lot of time away from building payloads and launching balloons....building and maintaining a flashy website is done with a maze of new languages seemingly expanding as fast as the Universe.

My main concern with wide coverage reports such as this is having a batch of folks launch balloons willy-nilly without regard to doing it safely. Ever since the MIT report, I've advised quite a few newcomers on how to do this safely (including advising the MIT students during their subsequent launches) and have actually introduced a few to amateur radio. I even suggested that the MIT students get their ham licenses and one of them has actually joined the ranks of amateur radio balloonists. This is a great way to get new blood into ham radio and the world of high altitude ballooning.

Let's welcome the UK balloon folks here with open arms as several of them are already on this list. They need all the support and good will we can supply them and I wish them all well in their endeavours.

- Bill Brown WB8ELK

6589. Re: [GPSL] NBC Nightly News

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-26 10:51:40 UTC
From: Ed Moore
Topic: 6579 Message: 6589

As a member of the Cambridge balloon group mentioned I should say that we definitely don't operate in a vacuum, a few of us are on the various balloon lists like this one (and would love to make it over to a GPSL one of these years). We're inspired (to name just a few) by the ambition of JP, the professionalism and competence of EOSS to have done this so successfully hundreds of times, and I'm saddened by the fact that I'll never be able to meet KD7LMO, having looked in wonder at his work since I started doing this a few years ago. That our particular group is working on a 100km rockoon currently only puts us on a path trodden by Bill and others several years ago (although I think I'm right in saying that an amateur rockoon hasn't actually made it over 100km yet? Hope so anyway :))

We've had our brushes with the mainstream media too - our teddies in (near)space project with a local school (http://news.bbc.co.uk/1/hi/7767376.stm) took off in a similarly unanticipated way with media outlets around the globe, and it's frustrating to have the 'near' stripped away from 'near-space' by every sub-editor, having our very carefully designed payload with our arm7 based flight computer become a 'laptop and webcam', and having the inevitable and ludicrous 'you could give nasa a run for their money' comments. But that's because, as Bill says, they're just interested in the notion rather than the actual details, and the details only matter to the aspergersey nerds like us (as they see it). My feelings after the brief media whirl is that it's really not worth the trouble and attention it (briefly) causes, and not nearly as much fun as teaching and working with the kids during the project itself.

I should make one small correction to Bill's post though, which is that we don't have to get our flights approved weeks in advance, or approved at all for that matter. We just have a blanket NOTAM for our launch site which gets re-issued every six months, and we can launch as and when we want provided that NOTAM is there (we call the local air traffic tower a few hours ahead to give them a heads up, more as a courtesy than anything else as we're near Cambridge Airport). If we had to get actual permission on a per-launch basis we would never be able to launch anything, because the jet stream forecasts are only really accurate enough to be able to ascertain a sea/land landing (i.e. whether or not a launch is feasible) about 48 hours before, and we would struggle to get any permissions in that narrow a time-frame.

Regards,

- Ed Moore (M0TEK)

You're right.

Mostly, it seems the balloon flights that get in the news do *less* than the typical ARHAB balloon payload. I suspect the media coverage is what these people mainly strive for. They probably spend more time writing their press releases than they do planning and building their balloon's payload.

> wonder if St. Louis can get the same coverage in May.
> Or all of us in July.
>
Apparently some of you want the attention of the media, but how many of you who launch balloons send out press releases for any of your launches? The press has hot-shot investigative reporters, but they generally cover crime and political issues (AKA "if it bleeds, it leads!").

The lowly science writers and other reporters that might cover a balloon launch aren't mind readers, they probably don't follow the Yahoo ARHAB forums, and they aren't likely to spot your balloon in the sky from their office window.

If you want recognition from the press, you should make it a practice to send out press releases prior to *every* launch. Eventually (OK, maybe on a slow news day) they may take an interest and come to a launch. It may be an eye opener for them if they come and see what's going on. Then you might even get more frequent coverage.

Go to nasa.gov and look for their press releases if you want to see examples of how it's done.

It also helps if you have some "gimmick" like the time one of our local launches sent up a package of "Peeps" with the regular payload. I saw coverage of that on ABC and CNN. When you are contacting news media about email addresses to send press releases to, check if they'll accept attached photos. Some of your photos from previous launches can be used to grab their attention, such as photos taken of the horizon from space or better yet one of those spectacular photos that catch the balloon in mid-burst, possibly a frame capture from a video.

It isn't difficult to get media attention, at least from the local media. I once called a TV station about a bogus "Water Testing Kit" I found rubber-banded to my front door knob. It was deliberately made up to look like something "Official" from the local government, but on very close inspection didn't have any mention of who really left it. It turned out to be from a well-known home water treatment company. The TV station sent out a reporter and cameraman to interview me in my front yard that very day. I didn't really want the on-camera interview, but I do hope I threw a monkey wrench into that company's deceptive advertising scheme. Point is, it just took one phone call to one TV station.

The local media frequently puts out their local stories to the wire services. So, your local balloon flight story may get picked up by national and international news services, but it doesn't hurt to directly send your press releases to the big-name news sources like CNN, The NY Times, USA Today, etc. Be sure to let them know if you will have video and photos available from your own sources, especially if you expect to have video from the payload.

If you get email addresses of people with the big-time media who appear to be at least somewhat interested, share those addresses with other groups who do ARHAB launches.

> I wonder if this is to make the public think of NASA as extremely outdated, so
> the President can sharply cut thier budget?
>
Actually, this President has *increased* NASA's budget. It was that other President that killed the shuttle but didn't fund building a replacement. The President and Congress have to provide extra funding during the development of new man-rated launch systems, but later the funding can come from the old program the new one replaces. Unfortunately, mostly what the politicians do is to constantly jerk NASA around with changing budgets and making NASA fritter away a lot of their funds re-planning and rescheduling their programs and missions to fit the constantly moving target which is their budget, and they can't build diddly until the goal stops shifting. Now, much of what they've already spent on the Constellation program will go down the drain with nothing much to show for it (I hear the design of the Ares I launch escape system has been mostly completed and might get used on one of the commercial crew launch vehicles).

If I remember correctly, NASA's funding is currently less than one percent of the "normal" Federal budget (not even counting the dilution of that figure by all the recent give-away funds to the failing financial companies with their obscene CEO bonuses). I think NASA does pretty damn good with what they're given and what with all the jerking around they have to put up with from congressional "investigations" (as if any politician knows his butt from a rocket engine).

Thanks Howard for your information, everything helps.
Hi Bill, the balloon is a 1500g HE. I set the ascent at 1000, descent at 1200 and the burst at 106000. As of this morning I would have to launch from my house in San Jose, (37.25356 -121.8877) The data source I've been using is MAE, FAT and NUQ.
Thanks,
-Ron K6RPT

Bill:

As you know I did file a comment on the story. My complaint was centered on Mike Taibbi in his lack of doing ANY kind of research on what has been done, not to diminish what has been done in the UK which is fantastic. I do not know what it would take to get amateur radio involved with it there but it would be a big help if they were allowed to participate. MSNBC did not originate the story, they picked it up slapped an opinion on it, demeaning NASA and the efforts of you Bill and all the people who have done these flights for the last 23 years. All it would have taken was five minutes to see if this had been done anywhere else in the world by using a search engine and or You Tube and they would have been overwhelmed. All MSNBC did was stick a end tag on the story and broke for lunch. Very shoddy reporting that you would expect locally but not nationally.
I agree with Bill in that balloon groups take the time to issue press releases. Extend your press releases to the Amateur Radio community as well as even many local hams may not be aware of your efforts. Your efforts may bring potential hams into your area and even help out
with the flights.

Subject: Re: [GPSL] NBC Nightly News

Hi Mark,

We think in similar ways...I just sent a comment to NBC News on that very link prior to reading your email with the link.

I do congratulate Robert Harrison on spreading the word about high altitude balloons to the world. I've been in touch with him and other balloon folks in the UK via email over the past year or two now and he does a nice job working on the modified FL-digi program as well as work on the SpaceNear.us balloon tracking program along with James Coxon. There are others in his balloon group that participate in the flights there from what I understand and there is also quite a nice balloon program at Cambridge. I would assume that he didn't intend the NBC reporter to make the statement saying he was the first to have ever flown a camera into Near Space (I emailed NBC's Mike Taibbi to correct him on that statement)...I know that many of you have flown that exact Canon Powershot camera for years now. The original report in the UK also stated he held the highest altitude record for weather balloons...that may be so in the UK but not the world as many of us have
exceeded his highest flight.

You have to understand bigtime news media....the story showing that one person can "beat NASA" for pennies compared to billions plays well and is somewhat of a editorial formula to capture the public's attention. Basically the same story was written about the MIT students and the Spanish students before that, the headlines were almost the same wording....but as those stories are months old, they are long forgotten by the very short attention span of the public by now so the formula still works.

The balloon groups in the UK have to surmount very difficult barriers to fly there. They have to approve their flights weeks in advance and they are not allowed to use amateur radio since the byzantine laws from their version of the FCC prohibit amateur radio in airplanes and balloons. As a consequence, they have to rely on 10 milliwatt 434 MHz transmitters running 50 baud ASCII RTTY...which is a challenge to track down for even the most experienced of us. They can't use the existing APRS network which makes our lives a lot easier here in the US. Add to that the problem of being surrounded by water and the good possibility of landing in another country.

As to some of the posts I read earlier being upset about the report since many of us have been at this for decades with very little recognition....If your local media isn't interested (although you might want to hit them up now that the skillet is hot), then my advice is to reach out to the world and start up a Wiki for your group in addition to your website...and post some of your favorite photos and videos there. Sooner or later some reporter will decide to do fact checking while doing a report and see what other groups are doing. We live in a world where flashy websites get the most attention and Wiki sites have become the online Encyclopedias of today (whether they are accurate or not). The main exception to this is the elegantly plain website of Google. If you want the general public to notice your activities and accomplishments, start with a flashy website along with a Wiki... post your favorite videos on YouTube and consider doing ballooning Facebook and Twitter sites. With these kind of tools, we now have an unprecedented ability to promote our achievements to the world right from our home computers. You might want to find someone in your group who is a web guru since keeping up with all this will take a lot of time away from building payloads and launching balloons....building and maintaining a flashy website is done with a maze of new languages seemingly expanding as fast as the Universe.

My main concern with wide coverage reports such as this is having a batch of folks launch balloons willy-nilly without regard to doing it safely. Ever since the MIT report, I've advised quite a few newcomers on how to do this safely (including advising the MIT students during their subsequent launches) and have actually introduced a few to amateur radio. I even suggested that the MIT students get their ham licenses and one of them has actually joined the ranks of amateur radio balloonists. This is a great way to get new blood into ham radio and the world of high altitude ballooning.

Let's welcome the UK balloon folks here with open arms as several of them are already on this list. They need all the support and good will we can supply them and I wish them all well in their endeavours.

OK
Here is how you comment:

http://www.msnbc.msn.com/id/29104230/

Be sure to mention the UK balloon story by Mike Taibbi.

Here is the URL for those that did not catch the story:

http://www.msnbc.msn.com/id/3032619/vp/36043526#36043526

Looking for a way right now to post a comment on the poor reporting of Mike Taibbi.

Any of you as disgusted as I am!?

The guy in England sends a Canon Powershot aloft on a balloon and it gets world wide acclaim for being the first to do this.

Is Amateur Radio soo antiquated that as soon as they hear the words Ham Radio or Amateur radio they all think we are stone age technology?

Man, I get soo pissed MIT and their cell phone big freaking deal, now this guy in england and his camera,

why is not any of the incredible missions we all do ever covered?

Very true, And with our group Near Space Sciences we have lots of help
from the local and non local hams. But up here in Wisconsin, if it has
anything to do with science, or technology, It must be done under the
umbrella of the University Of Wisconsin. If it is not. it is ignored!

And it's not like we haven't tried. we've sent pictures and actual
vdeos even to the local TV stations. Nothing, not even a reply.

One station we even have a in with, it's the local NBC affiliate of all
things. and the head engineer is a HAM too and he is even a part of pur
group at NSS. he has worked on some of the ATV payloads and has been on
the chase teams on at least 50% of the flights.

Even him working there as their head engineer, was not able to get them
to even make a 30 second blurb about the flights never mind even sending
out a crew to cover it.

The mentality up here is UW or U know nothing.

I forgot to mention: The story ran again this morning on the Today Show.
Lester Holt had to joke about "taking out a jumbo jet." Man, that's one
that gets old to me. And I like Lester!

We were hoping to do the same with the NSTAR flight that was scheduled for tomorrow at a severe weather symposium, but the rain and a forecasted landing in the Omaha metro has forced us to cancel. Bummer.

Did that alread last night like 5 minutes after the airing, nice letter
and video links to you tube examples of past flights.

as of this typing right now,, not a single reply yet. I'm gonna hit our
inside man again and see what he thinks.

From: Robert Rochte
Topic: 6579 Message: 6599

I have to agree with the comments about press releases and media contacts. They are certainly willing to pick up stories if you have a story to tell and can help make it relevant.

My flights at GPA have been covered by Mike Wendland (a nationally syndicated columnist for the Detroit Free Press and also a ham) including a mention in his MSNBC blog. Local papers have covered my balloons in a number of places where they have landed - and don't forget that CBC Radio did a live interview with both me and the fellow who found our balloon in New Brunswick a couple of years ago.

If you have a story to tell, the media will generally report it. But they're not monitoring this list and they're not checking APRS for a balloon aloft. So tell them about your flights, each and every time, and include the stories (i.e., the people) behind the technology.

The irony of this all just hit me.....

This is news to NASA? Isn't the guy who has been doing this for over 20 years, Bill Brown, a NASA engineer?

Actually - No.
Bill does work here on the Redstone Arsenal (where MSFC is located),
but not for NASA. He does have a NASA hat tho... but so does my Dad.

NASA is not new to balloons, the original pre-satellite balloon was a
big reflective gas bag that bounced radio signals back to earth.
Check http://en.wikipedia.org/wiki/Project_Echo

Check http://sites.wff.nasa.gov/code820/ (Wallops Island)
http://www.nsbf.nasa.gov/ (Columbia launch facility in Palestine, TX)

I'm sure some on the list know of these, but I'm sure many don't.
Talk about some big gas bags !!!

WOW ! - It's no wonder that Columbia broke up on re-entry...
I thought you could only go that fast outside of the earth's atmosphere,
or maybe better - outside of this solar system . . .

I'm not a direct employee of NASA. I have worked on several NASA funded projects over the years, a Marshall funded rockoon in the Gulf of Mexico and a Dryden funded balloon rocket glider also launched from the Gulf a year later, but mostly have worked on military systems at the Redstone Arsenal as a contractor engineer. I wear the NASA hat particularly when flying balloons that have been funded by NASA Space Grants.

6607. Launch site.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-26 22:35:29 UTC
From: k6rpt
Topic: 6607 Message: 6607

Hi Bill, the balloon is a 1500g HE. I set the ascent at 1000, descent at 1200 and the burst at 106000. As of this morning I would have to launch from my house in San Jose, (37.25356 -121.8877) The data source I've been using is MAE, FAT and NUQ. The payload weight is 2 lbs 9 oz.
Thanks,
-Ron K6RPT

6608. K6RPT-12 has been recovered

Yahoo group: GPSL (2009 — 2010)

From: k6rpt
Topic: 6608 Message: 6608

K6RPT-12 has been recovered. I was running in an orchard to catch it and it landed in a 15 foot tree above me, if the tree wasn't there I would have been able to catch it. The cross band repeater worked well. I still have to download the data from the BalloonSat Mini.

From: wb8elk@aol.com
Topic: 6609 Message: 6609

We tested out two new video cameras to see how they'd work on a balloon....the Tachyon helmet cam was flown by Jodie Tinker as an 8th grade science fair project...she won the regional with her first flight video and is now going to state competition with new footage flown today...and the second camera was the SPV micro camera that was discussed a week or so ago here on the list from Hobby Partz....it weighs just 18 grams....here's the results:

Here's a link to a photo gallery I just put together of some of the launch photos.

https://www.dropbox.com/gallery/4208641/1/BalloonFlights032710?h=9331b5&p=1

In addition there are some still frames I grabbed off the video taken with my 18 gram micro video camera....it was completely exposed to the elements and just held to the outside of Jodie's Science Fair payload with duct tape and lasted all the way up to about 33,000 feet before freezing up. Although low-res compared to a Flip Ultra camcorder it produces surprisingly good video and sound for such a small and cheap camera ($59 which included a 2 Gig microSD card). It's called the SPV camera and is used a lot in RC aircraft...I expect that with additional insulation and by adding an external battery pack it would work well throughout a balloon mission...it comes with a 2 gig microSD card that allows 2 hours of record time...but can handle up to an 8 gig card for 8 hours duration.

http://www.hobbypartz.com/smvicarewfr2.html

Jodie's helmet camera (made by Tachyon) worked great as you can see from the nice blackness of Near Space shots....this time she had it doing a still frame photo every 2 seconds....it was still snapping away at the landing sight so needless to say they have a boatload of photos to look at.

http://www.tachyoninc.com/

There are some very nice shots of UAH, the Saturn V rocket and the Space and Rocket Museum taken during the first few minutes of liftoff....you'll also note a jet zipping along with a nice contrail as we were at about 33,000 feet.

- Bill WB8ELK

PS...both payloads were recovered...SHC's was just east of Chattanooga and Jodie's was in the woods near Cleveland TN.

6610. HAB in the media

Hi all,

I'm rather embarrassed how much media attention the Icarus Project received over the last week.

Anyhow on CNN this morning I have tried to get across that there are many people doing this in the US on CNN this morning.

Hopefully you guys will get the recognition you deserve. I really have no idea why this when so viral...

Apologies all and wake your media guys up to their own backyard.

Robert, Great Job in providing a good AHAB overview, information and citing previous AHAB history in the report on CNN! My hat's off to you to set the record straight. Again, Great Job!

My biggest concern was not with the bad reporting regarding your achievement as much as the spawned interest resulting in others going out and launching balloons without concern for the safety of others - (balloon boy - lawn chair man) - and work with the fact we share our airspace with a lot of aircraft that also have a right to be there. You have to admit the "Wow!" factor was high (no pun intended) which would draw a lot of people to launch balloons in a very uninformed manner.

As an airplane pilot and AHAB team member, I am so very, very happy you mentioned the needed coordination with the FAA. On every one of our flights, the FAA have great to work with, but also genuinely interested and facilitating in all aspects of the flight. I feel it is imperative that we continue to involve the FAA or equivalents in other countries to keep this AHAB privilege alive. It will only take one strike or near miss from any commercial aircraft that had no idea the balloon was in shared airspace to ruin it for all of us.

I am not sure what is used in the UK for flight coordination, but here is an overview of what we do for ARBONET flights, along with issuing a NOTAM:

http://www.arbonet.net/FlightSafety.html

Hi Robert,

I think everyone else was surprised as well, especially given the lack of interest most of us have experienced from the media. Nobody really begrudges you the coverage, though - you obviously got success in that area.

Most of the "disappointment" was the lack of context in the coverage, which was not of your making. That's the added value the reporter is supposed to provide, otherwise he may as well send press releases straight to air.

We high-altitude balloonists in the US are fortunate to be able to use ham radio so freely for our balloon payloads. To make a go of it at all, given the constraints UK high-altitude balloonists face, is pretty impressive - you guys really have to push the envelope to make it all work (not to mention being surrounded by nearby water!).

6614. Balloon Nozzle Plug

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-30 00:33:11 UTC
From: Pete Lilja
Topic: 6614 Message: 6614

Having borrowed the idea from Mike Manes I have machined several balloon nozzle fill / plug PVC fittings like linked here:
http://s33.photobucket.com/albums/d94/bigheadpete/?action=view¤t=IMG_0008.jpg
These things have worked really well in the 1200 gram balloons we've flown using this system.

If anyone would be interested I have gotten my machining technique down so that I can make these relatively quickly and easily. If anyone would be interested in having one I'd be happy to make some more and send them for the cost of materials, postage and the envelope which would be around $5 / ea. in the US.

If interested email me:

Pete: plilja at cfu.net

Thanks,

Pete

During "Morning Edition" today, they ran a BBC interview with the UK balloonist, who kink of poo-poo'ed all the attention, and pointed out that he'd drawn heavily on many of the US ARHAB web sites, and even named our very own Bill Brown as having taken thousands of similar pictures over the years.

Nice to get some professional journalism every now and then.

Hi Pete,

Wow! That's a pretty deep cut, but it sure does make for a good grip
on the balloon neck, and it also makes a nice, flat flange for the lift
line, to boot. Nice work!

From: Pete Lilja
Topic: 6620 Message: 6620

As I've mentioned several times before I also have the hobby of flying rockets. One well known rocket flier / builder has created a pretty cool app. for his flights.

What he has done is created a computer program that uses the voice of 'Kate' to narrate his rocket flights in real-time. As I understand it his on-field laptop simply receives the telemetry data from the GPS / transmitter equipped rocket and the voice of 'Kate' narates the flight aloud in real time. You can listen to recordings of some flights and get a better idea here: http://www.vernk.com/PhotosOfAngelfire.htm

I'm not computer savvy enough to do the same but I'd bet there are HABists here that are. Not only is it pretty cool and fun I could see it being helpful while driving to recover a HAB payload.

Just thought I'd share this. Take it for what it's worth.

OK, now this is cool. I'm not really into these 3 or 4 minute rocket flights but narrating it in real time is very cool. I'd love to do this with our balloon flights. Use one of the output ports on Xastir to feed the telemetry into the script running the voice synthesizer on my Mac.

I'm working on a similar thing for a NSTAR flight this year, except it will narrate it from the balloon on 446.30 MHz. It'll read off lat, lon, course, speed, altitude, and ascent/descent rate. This was inspired by the ARBONET flight at GPSL last year, who have something similar.

The hardware to do this consists of an Arduino, a WaveShield to interface an SD card full of voice snippets, and a GPS. You parse the GPS data, decided what phrases to say, then tell the WaveShield to play them on the radio.

Now that is pretty cool,

Does the audio come from the rocket? or from the ground decoded from
telemetry that came from the rocket?

6624. ARBONET Voice Beacon Sound Track

Yahoo group: GPSL (2009 — 2010)
Date: 2010-03-30 16:18:43 UTC
From: Michael Willett
Topic: 6620 Message: 6624

The ARBONET voice beacon uses an Grand Studios Emic Text to Speech module. These have been discontinued, which is sad, they are very nice units, even at $75.00...

Here is an example of the ARBONET voice beacon, it plays in the background of this page if your ISP and browser allows it to play:

http://www.arbonet.net/ARBONET%20TRACKING.html

This is off of a receiving radio / PC using scanner recorder at my home about 100-120 miles from the flight. My audio is slightly over-driven, but it is still quite usable. I don't have the GPSL recording handy, however I feel it was quite a bit clearer.

I can send the example MP3 to you direct if you can't listen to it on the web page.

That sounds good Michael.

I wonder if its better to have the electronics in the balloon doing the voice stuff or would it be nearly as good to just have it local at the laptop. Obviously if it's on the balloon then everyone can hear it, but on the other hand it's more electronics, more batteries, more cost, more to lose, etc.

Just a conversation point, I have no opinion of my own yet.

The ARBONET 1 flight voice beacon was a team effort, I designed and assembled the hardware and a friend of mine, Mark Culross KD5XRTof the Lockheed club stepped up to the plate and debugged the hardware and worked diligently on the programming. It was great to see the plan come together and anyone with a 2 meter radio or scanner could listen in on the action. I think another motivation was that I was having a hard time getting APRS in my truck! :) It will be a part of as many ARBONET flights as possible in the future.

I've wondered if we could incorporate this into a FRS radio and get the
range so anyone near the ground track could listen in the mission.

Perhaps by modifying the antenna on the FRS radio? Is that even legal?

Hi Everyone

I've built a program to do exactly this. It's really designed as a telemetry "dashboard" application. It displays Lat, Lon, Speed, Course, and climb/descent rates. It also calculates a prediction of where it will be in one minute, primarily for landing prediction. It also speaks the altitude with each report using MS text to speech. It's was originally designed with UI-View in mind but I made it more generic now and it will work with any program that will accept an telnet connection on port 14439. It also reports the telemetry from my OpenTracker based tracker. All of the settings are hard coded so it's not very flexible yet. My next step is to change it so it records the configurations in an external file or in the registry. It may even accept updates over the air based on the APRS telemetry standard.

I'm attaching a snapshot of the program interface. I'd be glad to send anyone on the list a copy if they want to give it a try. If anyone is interested in the source code, I can also send that on an individual basis. If anyone is interested in assisting with the development, I probably wouldn't turn you down.

Looks very ambitious and good luck to them. Though, I'm a bit tickled by how corporate they seem for a bunch of master's-students-come-radio-hams. I say that as a masters-student-come-radio-ham.

The flight computer is described as "Our design builds on past success while fostering innovation by utilizing the next generation Atmel XMega microcontroller." - which sounds like the kind of thing written in industry pamphlets for large corporations that no one reads, and their team structure diagram (http://www.projectbluehorizon.com/index.php?a=team) is straight out of a large multinational insurance company (c.f. http://www.prudential.co.uk/prudential-plc/aboutpru/ourpeople/structure/).

Whilst I suspect there might be a little that's not being said on their website (I honestly don't want to stir, but it doesn't take much googling to see that this seems to be a training program for employees of one of the world's biggest multinational aerospace and defense companies, rather than an amateur project), I shall track their balloon with interest and try and contribute whatever telemetry I can from the other side of the pond.

Good luck PBH!

wow great ideas, out there, I remember chasing UTARC-3 without a TNC because the PIC spit out the telementry in voice over the radio from an SD card

Now you could reduce parts by using a SpeakJet chip.
http://www.magnevation.com/pdfs/speakjetusermanual.pdf
just send your incoming GPS position in ASCII serial(converted by any controller) to the SpeakJet and the chip does all the voice and sound generation to the chip speaker (radio mic)

if you want to do it from a ground computer. I've done something similar (not for ballooning) with ReadPlease from IBM a free software that reads text in 4 different voices at any speed.
I took my text stream and using Batch I converted the file extention from .txt to .rs or .rps opened ReadPlease sending it the file which was read automaticly to the speakers in the set voice.

Sincerely,
Carlton

Back in 1992 I launched a balloon that send down the telemetry with my voice generated by the then brand-new ISD chip that ultimately made it into Hallmark cards and just about anything that talked then. You could portion off different memory spots on the chip and address each number that you wanted to send down...I basically just recorded the number 0 through 9, my callsign and "balloon" and could send each one by the addressing them on the chip. I was just going to mention the Speakjet chip that Carlton posted....I just got one but haven't tried it yet....looks like it'll make life easier to implement voice messaging.

I still have an ISD-based voice telemetry system that Robert Rau N8IYD and I built up for the Earthwinds round the world project...it only flew on that massive system once and they didn't stay up long. Their gondola weighed about 22,000 pounds as I recall.

wow great ideas, out there, I remember chasing UTARC-3 without a TNC because the PIC spit out the telementry in voice over the radio from an SD card

Now you could reduce parts by using a SpeakJet chip.
http://www.magnevation.com/pdfs/speakjetusermanual.pdf
just send your incoming GPS position in ASCII serial(converted by any controller) to the SpeakJet and the chip does all the voice and sound generation to the chip speaker (radio mic)

if you want to do it from a ground computer. I've done something similar (not for ballooning) with ReadPlease from IBM a free software that reads text in 4 different voices at any speed.
I took my text stream and using Batch I converted the file extention from .txt to .rs or .rps opened ReadPlease sending it the file which was read automaticly to the speakers in the set voice.

Sincerely,
Carlton

I'm working on a similar thing for a NSTAR flight this year, except it will narrate it from the balloon on 446.30 MHz. It'll read off lat, lon, course, speed, altitude, and ascent/descent rate. This was inspired by the ARBONET flight at GPSL last year, who have something similar.

The hardware to do this consists of an Arduino, a WaveShield to interface an SD card full of voice snippets, and a GPS. You parse the GPS data, decided what phrases to say, then tell the WaveShield to play them on the radio.

The ARBONET voice beacon uses an Grand Studios Emic Text to Speech module. These have been discontinued, which is sad, they are very nice units, even at $75.00...

Here is an example of the ARBONET voice beacon, it plays in the background of this page if your ISP and browser allows it to play:

http://www.arbonet.net/ARBONET%20TRACKING.html

This is off of a receiving radio / PC using scanner recorder at my home about 100-120 miles from the flight. My audio is slightly over-driven, but it is still quite usable. I don't have the GPSL recording handy, however I feel it was quite a bit clearer.

I can send the example MP3 to you direct if you can't listen to it on the web page.

That is what late night programming will do to you, - you have "GPS lost lock" as the voice indicator initially, but getting punchy late at night you think about the female voice and start adding things maybe you shouldn't, so you end up removing the comments about being a blonde and leaving the "Once again I am so very lost" part. There was also a mode where it was supposed to say "I will stop and ask for directions" when it regained lock and I think it only said that once on that trip.

I still remember exactly where I was sitting at the group dinner when you told me that the Copernicus GPS required a register setting to allow operation above 60K feet. Staying up until 3AM trying to get that to work resulted in a lot of bad mistakes the next day and a long flight that actually did get lost for a week...

The Inventek is on my new board. That new board with many upgraded sensor and processor features arrives today.

6635. GPSL Update

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-01 17:02:24 UTC
From: Zack Clobes
Topic: 694 Message: 6635

The GPSL plans are starting to come together. Hopefully the website will be updated in the next couple of days, but there is one matter I'd like to bring to your attention. Apparently, someone decided to plan a softball tournament on "our" weekend in Hutch, and consequently, the hotels are filling up very quickly. I had hoped to find an "official" hotel for us all, but I'm afraid that may not be practical under the circumstances.

So, if you plan on attending, and haven't already made arrangements, please do so SOON.

Some hotel information:
Hampton Inn - FULL
Holiday Inn Express (620-669-5200) - About 10 rooms available
Day's Inn (620-665-3700) - About 18 rooms available, but are mostly smoking rooms.
Grand Prairie (620-669-9311) - Fair availability, depending on the exact nights you want to stay.
There are plenty of others, these just happen to be ones that I'm vaguely familiar with.

A quick note about the Grand Prairie: It tends to be a bit more pricey, and I know that some weren't that impressed with the room and the pool-side noise last time. I got to visit some family at the GP a few weeks ago. They were staying in a room on the north end of the hotel, away from the pool. The room seemed nice and clean, and it was well away from the pool noise...

Zack,

1) What do you want me to update on the web page?

2) Would you like to show the BLAST! movie again, like last year?

How many cubic feet of gas in a 'K' tank?

How many cubic feet of gas does it take to fill at 1500g balloon?

http://linweld.com/cat/29.pdf

K tank is 219 cu ft.

When we fly a 1500g balloon with our usual 8-9 lb payload, we put almost all of a T tank in it. Sometimes we short it a little if we want under 1000 ft/min, but if we dump the whole thing in we don't have to worry about an underfill.

According to the web...

K tank = 219 cu. ft. of helium (this varies a bit from place to place).
Follow this link, click on He pure and the PDF will detail how Linweld
delivers in a K tank.

http://www.linweld.com/puremix.asp

Kaymont Totex 1500 gm balloon fill volume 3.3 cu. Meters (116.5 cu. Ft.)

http://www.kaymont.com/pages/sounding-balloons.cfm

However, we don't usually fly with minimum weight so, more helium is needed.
How much more, depends on your flight system weight.

OK, so theoretically one 'K' tank of H2 (Hydrogen) should fill our 1500g balloon.

We are going to use H2 instead of He.

A lot will depend on your weight. With H2 and 6 lbs or less, you're probably OK with a K.

The volume quoted by Kaymont for 1500g is probably for a NWS standard radiosonde which is not more than 1 lb I think.

You may want to check the LiftWin program at http://www.eoss.org/dnload/liftw-041.zip to run your own numbers to see if the volume is enough.

Hi Keith

You can find the Visual Basic 3 runtime dll in literally thousands of locations on the net including http://www.xmission.com/~psneeley/Shareware/VB300.htm Just toss it in your system or system32 folder and you'll never have to worry about it gain.

I've never had to find some obscure missing module to make a Linux app run, or have I .... Sorry, that was my sarcastic side coming out. My wife says I should behave myself.

Hi All...just saw the discussion....I emailed Keith that 6 pounds (as Mark just mentioned) was the payload/parachute weight combo I'd recommend for a K bottle using a 1500 gram balloon. You could fly with just a few ounces of positive lift but then your ascent rate will be near 400 ft/min or below and you run the risk of a long duration floater flight....and yes LiftWin is the tool that will show the helium or hydrogen volumes that you'd need. I'm rewriting my old DOS Ballift program which does a similar thing as LiftWin and will shortly have it available on my website as a Windows program soon.

A lot will depend on your weight. With H2 and 6 lbs or less, you're probably OK with a K.

The volume quoted by Kaymont for 1500g is probably for a NWS standard radiosonde which is not more than 1 lb I think.

You may want to check the LiftWin program at http://www.eoss.org/dnload/liftw-041.zip to run your own numbers to see if the volume is enough.

Attachments: 1 described; binary payloads are missing from this source WARC

I have been discussing this with Bill The main Man the balloon dude of all balloon dudes. And want to also open this to any of you out there.

What do you do when in your flight train the balloon is many times heavier than the rest of the flight train?

What do you do to keep the balloon schards remenants from dragging the chute over upside down since it would weigh much more than the payload?

Hi Joe,

EOSS uses that fast release device that you made a prototype of to
get shed of the shards immediately after burst. Another way is
to fire the cutdown while the balloon is still intact, but sacrifices
hitting your peak altitude.

Joe,

Although we've never flown light payload strings (too many experiment on the flight), I wonder about flying with an inverted parachute. I can envision a stack that has the balloon on top, then the payload and at the bottom the inverted parachute.

The ascent would be slowed at lower altitudes (another fascinating Hanks' knee in the climb), but after burst I believe you would exit the chaos with the chute on top and working properly.

Of course, I've been wrong before :)

Howard

From: Michael Willett
Topic: 6646 Message: 6651

Bill's the expert here, he has done flights like this as controlled experiments. From a personal learning experience myself, (similar to fumbling around uncontrolled in the dark) make sure the space between your balloon and the inverted parachute is enough that the balloon's free-fall won't drop into the center of the parachute and make one big tangled mess. :) Experience indicates good spacing is needed here. We flew an inverted chute at GPSL and among many mistakes that late night before and on the day of the launch, I had only about 6' between the balloon and the parachute, and you probably want something more like 25' to give the balloon residual a smaller relative target to hit on the initial fall.

You might consider a drogue chute to pull the main on your payload to really reduce the footprint of the inverted chute while the balloon residual passes by on the way down, and to help increase your ascent rate. The main parachute will provide a lot of drag until it arrives in the ineffective reaches of the atmosphere where it will eventually deflate and hang freely. Our chute became ineffective at altitude also due to being in the draft of the balloon itself which has now increased in size a great amount - our chute was only about 6' away from the envelope.

On the way up, the Hank's knee Howard talks about below will be affected considerably, since your inverted chute, if left without constraint, will open on ascent and cause a great deal of initial drag. It provides a more logrhythmic ascent rate initially. Our 90 minute flight went about 3 hours up and went way long down-range being stuck in the higher winds aloft area of the ascent for a longer period of time. However, the chute becomes very ineffective at altitude, so the ascent does start to get back to a normal linear flight ascent sometime shortly before burst. :)

Days like that day at the GPSL really humble you from "We learned something really neat from a really great flight!" to "We really screwed up and we also lost our payload!". But we did get some cool, unexpected data. (And we gained another, possibly useful tool in how to slow the initial ascent rate...)

Doug, (W5BL) and I laughed so hard on the way back from losing the payload that I nearly had to pull over on the road to wipe the tears from my eyes from laughing so hard. Our female voice beacon went off in firmware lala land and would not shut up during the flight and gave us a continuous rambling with no useful data on where the payload was located, also wearing out the system batteries... You can imagine our comments and why we laughed so hard...

Thanks for pointing out that easy solution to Keith.

I guess I should create a new LIFTWIN website that explicitly
includes VB300 as a small download as well as the instructions,
screenshots, and supplementary notes that were available
at HABLIC for years and would still be there if Geocities/Yahoo
hadn't folded as a free web hosting service about a year ago.

>> I can't run that program, I'm missing some parts, specifically
>> VBRUN300.DLL, and people wonder why I hate windows.

For the record, I'm not aware of any parts with an "s" that
could be missing. It's just that one VB runtime module beside
the exe itself, that's it.

This program runs on most slightly older editions or variants of windows including WIN2000 and XP without needing to add anything.

Hank

Howard...Arbonet did exactly this configuration last GPSL....it was a very slow ascent....if they have some GPS data up to the point where they reached the 27,000 foot or so limit on the Copernicus module (in Ground mode)....then it would be interesting to plot the ascent to see how it varied with the inverted parachute. I had some of their data plotted last Summer on my computer but lost all that data when my computer was stolen from my house.

Hi Joe....THe Mojave desert is an interesting place to fly...I did my first flight there in 1989 from near Victorville, CA. We tracked it with not only a chase plane but a chase helicopter (flown by W6ORG). It landed in a sand dune near Barstow and the helicopter just swooped down to recover it...everyone else had to hike in quite some ways from the nearest road.

Here's a YouTube video of that flight:

How crude. You actually had to use airplanes and helicopters to recover it!

(That was a huge tongue-in-cheek remark in case anyone missed my humor.)

Actually, that is pretty darned cool. That seems a long time ago, I'm sure. Pre-GPS days and, I'd guess, RDF only. A far cry from my GPS / ham radio set-up that directs me right to where the payload lands these days.

Pretty cool, Bill. Thanks for posting.

Hi Pete....yes, that was way before GPS receivers so we used Direction Finding to guide the chase plane to the landing area....as it parachuted down we lost the ATV antenna....the chase plane had ATV onboard and as I guided them into the area where I thought it would be coming down, they started to get a stronger and stronger picture on their TV....I was amazed since I had nothing at our ground station....Mike WA6SVT inside the chase plane said, "Hey, I see the same area on the video that we are flying over, it's a perfect snow-free picture..very strong signal....there's the lake, a house, an airplane wing!!!!"...and whoosh, it zipped right past their wingtip. They watched it land in the sand dune as the helicopter swooped in.

How crude. You actually had to use airplanes and helicopters to recover it!

(That was a huge tongue-in-cheek remark in case anyone missed my humor.)

Actually, that is pretty darned cool. That seems a long time ago, I'm sure. Pre-GPS days and, I'd guess, RDF only. A far cry from my GPS / ham radio set-up that directs me right to where the payload lands these days.

Pretty cool, Bill. Thanks for posting.

Pete

The following is from Luther Richardson, KI4AOJ:

DREAMS: Doing Research at Extreme Altitudes by Motivated Students. DREAMS is a project of NASA Ames and the Georgia Space Grant Consortium. DREAMS' eighth launch took place recently in Mojave Desert, California.

The DREAMS-8 Flight flew to about 90,000 feet and recorded data from our electric field mill and some other sensors.

Images and flight video can be found at http://mojavescience.columbus2space.org/.

5th graders from Rob Palassou's Science Club in San Francisco, CA ran the subsystem checks for launch and released the payload. They also were the ones who recovered!

That makes for a terrific story with the chase plane seeing themselves fly by. That's kinda one of those mind-benders that probably took a minute or two to orient their minds to seeing themselves flying by.

From: Mike Manes
Topic: 6646 Message: 6658

Of course, there's also a pretty fair chance that your payload string
would fall right into the 'chute canopy for a REAL fast ride home.
This has happened to EOSS and even JPL without doing it on purpose.

The good news is that short descent will compensate for the long
ascent.

Yup i remember all the flights were RDF and triangulation. The ultimate
Fox hunts!

I remember our first GPS unit. the antenna was still even back then
small like 2" square or so. The GPS unit tho, was a unit that had
three PC board layers that were double sided components, and was like 4"
wide by 10" long. And that was still only the GPS, you still had to
dump that into like a Kantronics KPC2 or similar and then dump that into
a radio too!
wow!

6661. RE: [GPSL] Flight Train.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-03 02:57:56 UTC
From: Nick Hanks
Topic: 6646 Message: 6661

In 2007 GPSL was held in Grand Island, NE. One of the groups attending was from Maine. I believe the group was EOSRED ☐ Edge of Space Research, Experiments and Developments (http://groups.yahoo.com/group/EOSRED/). They launched in interesting configuration. They had two balloons (about 1000g or 1200g I think) and on the bottom of the payload string they had an inverted parachute. It may have been made of a metallic-coated cloth. After the flight at the ☐How Did It Go☐ session on Sat. afternoon Lee W1LWT explained their configuration. This is what I remember they said. Maybe there were others who heard Lee that can add more detail and/or provide some corrections. Or maybe W1LWT monitors this reflector.

They flew two balloons because the prevailing winds in Maine often blew their balloons out to sea. One balloon would of course burst at a high altitude, leaving the other balloon inflated. The second balloon didn☐t provide enough lift to generate a positive rate of ascent with the shards of the first balloon and the payload string still attached. (It may have been under-inflated.) So the second balloon and the payload string came down (albeit slowly). I believe they had the inverted parachute on a short line (five feet maybe), and it got tangled in the payload string. As I mentioned, the whole thing could land in the water. If it did, instead of sinking, the second balloon kept everything afloat until EOSRED folks got there in a boat. They said they needed the inverted ☐chute to keep the ascent rate down with two balloons providing lift. The parachute wasn☐t used to slow the descent.

73,

Nick

Subject: Re: [GPSL] Flight Train.

Joe,

Although we've never flown light payload strings (too many experiment on the flight), I wonder about flying with an inverted parachute. I can envision a stack that has the balloon on top, then the payload and at the bottom the inverted parachute.

The ascent would be slowed at lower altitudes (another fascinating Hanks' knee in the climb), but after burst I believe you would exit the chaos with

the chute on top and working properly.

Of course, I've been wrong before :)

Howard

Hi Joe,

EOSS uses that fast release device that you made a prototype of to
get shed of the shards immediately after burst. Another way is
to fire the cutdown while the balloon is still intact, but sacrifices
hitting your peak altitude.

We did the two balloons , but inflated them so they each provided 1/2
the needed lift. and one would eventually pop before the other, and then
there is only 1/2 the needed lift to stay airborne so it comes down slowly.

it make it awesome to find them after landing, as long as the wind is
slow. if it's windy it's gonna get dragged till it gets caught on
sometyhing.

Or until a weak bit on the payload string breaks off, thus unburdening
the balloon so it takes off again. It's happened to us twice! The
good news is that you get an extra launch at no extra cost :-}.

I participated in a flight with 3 balloons out in California with KC6CCC....two burst leaving one inflated on the way down. We could see the one balloon sticking above the treeline as we approached a popular ATV off-roading site....all of a sudden the balloon disappeared and we shortly saw a fellow in his truck with our payloads in the back next to his ATVs pass us in the opposite direction as he was heading to find a payphone to collect the reward. We flagged him down but still had to pay the reward.

There's a near space photo in sky and Telescope this month (May).

Page 97 is the Gallery page, where amateur have their astronomical pictures displayed. Greg Merkel and classmates from the University of Minnesota's Spaceflight with Balloons class launched a mission with a Canon Powershot A570.

Congrats.

Do we know this class?

6666. Battery Packs.

Yahoo group: GPSL (2009 — 2010)

Wow not sleeping at night is NOT the time to start to work on a new payload!

I was as usual up last night up at 2 AM not sleeping, And decided to start working on a new payload. not a good idea to do when half asleep and in a room that is only lit by the light of the computer monitor.

On the top shelf of the book case is a group of used LI-Ion Battery packs from previous flights. I use them when building new payloads to power then for testing etc. so not to waste any energy from a new pack. Even tho these packs have soo much power they probably could fly two flights anyway. I have drawn well past an AMP of power from them, and done so for over 12 hours and the output voltage would have dropped still only a volt or so max! Out of 15 volts! Anyway these are those Old packs from way in the beginning of this ballooning stuff. Some of you old timers here will remember these guys. Some sort of military pack. inside was 10 "D" sized cells. made in a like 30 volt center tap configuration, They were easily split to make you two 5 cell 15 volt packs. They looked like this,

If the group strips images (I don't remember if it does or not) the image can be seen at,
http://i40.tinypic.com/zunudk.jpg

Well after grabbing the one on the right, (obviously older) There is ohhh six to eight other sub packs like these up on that top shelf. up there. It's across the room from the workbench here. I sit down and check the voltage, still 15.2 cool,

then suddenly HISSSSSSSSSSSSSS! is coming from the bookcase!

In moving the old pack I somehow must have shorted out one of the other packs!

It's LOUD, and not sure what the gas is that it's spewing out. All I knew is that in literally seconds from the time the hissing started, I now can hardly see, and can not breath at all, any of this gas in your lungs causes an un controllable coughing, which of course sucks even more of this gas into your lungs causing it to be even worse!

I run out of the room and slam the door shut as I leave! Coughing and gasping in the living room, I'm now getting quesasy, well not quesasy,,,,wrong word, queasy is like barfing, no this is more like the state of being at the dentist with happy gas level of consishnous, but without the "Happyness!" I'm like 50% passed out!

I don't know how much time passed by but i'm more alert now, but then it hit me, about stories I remember way back when we first started using these incredible high power packs how if they get shorted be sure they are fully fused, because they have so much power they can literally catch on Fire or even explode!

Thinking wow I gotta get that pack out of here! I run into the bathroom and make a damp towel and try to enter the room.

Wow cant breath it at all, thats for sure. and promptly leave the room because the eyes are burning BAD and I can't see anything at all in here!

Wow, I re group, and try again, a deep breath and closed eyes I re enter the room. and get to the shelf, but now what pack is it? Remember there are like 8 of these things up here! I cant tell. none seem hot, weird! well I wrap a couple in the towel so they don't touch each other and run outside.

All packs are cold! must be another. I go back in and get another two packs. and take them outside. Nothing still all cold! WTF!!!

Well one more trip and I have them all outside now. So at least i don't have to worry about my house burning down!

I now start to examine each pack. and finally find the pack that did it. and it was just one cell!! one of the connection wires shorted out just ONE cell! All this came from just ONE CELL!!!! WOW Only one cell is warm, all the rest are stone cold! can't imagine what it would have been like if all 5 were shorted!

Whats even more amazing is the packs voltage is still 14.8 volts!!!!! WOW!!

Now Ok the fire hazard is gone. but even with the bedroom door being closed the smell is still starting to creep through the house!

This is an old house and has old fashioned storm windows you install in the winter. But unlike most that install on the outside, these install on the inside and in an un convient way. it takes like 10 minutes to install or remove. so opening the windows is not going to be a option.

Luckily this bedroom is at he end of the hallway and right next door is the bathroom. the doors actually touch each other.

I close my master bedroom door, to help keep the smell out, Lindas still sleeping in there he he he.. and I open the bathroom window, and install a fan on high blowing out.

I open a window at the other end of the house so the airflow is from the far end and then out through the bathroom window. (isn't that a Bob Dylan Song?)

And after the hallway has no more strong smell I crack open the stinky gas chamber room, and start to let the smell out. it gets sucked outside, this is working great!

after a hour or so i'm able to have the gas chamber door wide open and keep ventilating.

after a hour it's not too bad anymore, and I finally go to bed, In the process I wake Linda up and she says what the hell is that smell! he he he I had to explain what all has happened for the past few hours! he just shakes her head and says go to sleep.

Well this morning 90% of the smell is gone but it's still in here. in the background. it reminds me now of doing B&W darkroom photography work with the developers, chemicals and stuff like that.

So after over 20 years of doing these flights and using these packs, this is our first accident so to speak. Wow guys. respect these high power cells if any of you have any of them still laying around!

Cough,, cough!!

SigOn ORB-14 I used a 2-cell Lithium Camera battery for the cutdown. One of the cells vented during flight. It was pretty evident at recovery when I opened the payload. The smell didn't go away for about 6 months. I got in touch with Eveready and they told me what the gas is. The following is from my ORB-14 post flight notes.

Tue Oct. 26 1300
I have been in contact with Eveready and they have been very responsive and helpful. The gas that was vented is called DME, Dimethoxyethane, or 1,2-Dimxyethane, or Ethylene Glycol Dimethyl Ether, which smells like Ether. It is a flammable vapor and is non-corrosive to equipment. All Lithium batteries vent this gas, but in such small amounts that it is not normally noticeable except when contained in a small air tight enclosure. Altitude may have been a factor in
the amount of gas vented. I am waiting for a call back on that. I was told there is a company by the name of Gore that makes a permeable plastic membrane that will suppress the odor. I have not found them. I wonder if Tyvek would work?

Hi Joe,

I still have about a half dozen of these packs as well...some are in my house and most are in the garage....I'll be putting them all in the garage now inside some metal military ammo cases (lined with plastic of course). The battery pack on my first live TV camera payload from 21 years ago still powers up with full voltage from it's original pack even after doing a 4 hour flight.

I did something embarrassing at work a few years ago during a big demonstration of our robotic vehicle in front of a lot of military brass. I brought along a spare high power battery pack that had two big metals connections tabs on the top of it in case we needed it for the demo. Inside the shelter we were using for our command center (it was very dimly lit so that the computer and video screens would have good contrast), I saw what I believed to be a pile of concrete blocks....I set the battery pack upside down with the terminals sitting on the "concrete blocks". The entire battery pack immediately started to glow bright red and emitted smoke and fumes with a hissing sound...I tossed it outside as the brass and all the engineers ran out of the shelter.....upon inspection with the lights on, what I had thought was a pile of concrete blocks were in reality large blocks of solid metal ingots that they used to shim up the equipment inside the shelter. Even after pulling 200 to 300 Amps through this pack...it still worked after it cooled down.

6669. Re: [GPSL] Battery Packs.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-04 01:40:29 UTC
From: Michael Willett
Topic: 6666 Message: 6669

One of my first jobs out of college was to work at Ampex Corp in California. One of my first assignments was to figure out how to make a safe video tape recorder battery pack for a portable video tape recorder - the model VPR-20. It turned out at one of the previous designs blew up and took out a video studio room with a fair cost to the company I now worked for.

The design did not take into consideration that NiCd batteries in a fully enclosed metal container will vent hydrogen when the cell goes amuck, and this enclosed area (just like an ammo can) kept the gasses within the container. When the cell went thermal, the hydrogen ignited and the can basically became a grenade. Shrapnel went everywhere. We were lucky this happened when the studio was not inhabited by workers and the pack was on the charger.

So my first job was to find out what happened and fix this previous design. I pretty much figured out what happened after a week of research and testing... I went to GE battery in Gainsville, FL and toured the plant that made the batteries and worked with the engineers for about four days to come up with balanced cell battery packs, all individually fused and with thermal protection to open the circuit if the cell got warm, (warm being not even close to boiling). NiCds get warm when the cells reach full charge. When charging fast (1 C or above) you need to sense this and reduce the charge to 1/10C. So a new charger design revision came along with the battery pack design that charged not by time and voltage alone, but by time, voltage and temperature sensing.

The new enclosure was well ventilated, strong plastic (not metal!) and I added a small fan that would run during charge and discharge to expel the gasses if the safety measures in my design by chance failed. After every abuse we could think of, we could not get the batteries to explode again, and the new pack went into production based on a far more informed, respectful design. I have had a very great respect for all batteries ever since - and fuse at the battery pack itself as well as at the load location to assure the battery and load are both protected properly. You will see this set up in my truck for my mobile radios as well, as batteries have a tremendous amount of power! Even the high impedance Lithium Thionyl Cloride batteries we fly on ARBONET are fused this way. If you short one of these out, believe it or not, they can get so hot you can get a spontaneous fire. So each battery implementation needs two viewpoints at minimum, one looking at the battery itself - fuse at the greatest load it should ever see, and then at the load, fusing at the greatest load it will ever pull. This allows for multiple loads on a protected battery source.

My batteries are all stored in Styrofoam layers with ventilation, leads protected from shorting and in an area of the shop that is ventilated and close to the door. :)

Hi Joe,

Those are LiSO2 primary cells, IIRC, not Li-ion, which are rechargeable.
And yeah, I remember the bad ol' days when I had to grub out a fresh
set of cells from those mil surplus 1-cell packs. I never encountered
a shorting event, but one of the EOSS old-timers did accidentally short
a 5-cell pack on his bench, and dumped a fire extinguisher on 'em.

Not that Li-ion's are any safer - if you short out an 18650 cell, the
results are likely to be similar. But since the Li-ion pack needn't
be opened regularly, one can apply plenty of insulation and mechanical
protection on the pack AND its accompanying protection circuit. The
protection circuit guards against overcurrent, overvoltage and undervoltage,
and anyone who uses Li-ion for payload power without a protection circuit
is ... well, I really can't use the proper term in this forum ... asking
for trouble, shall we say.

BTW, the reason we shifted to Li-ion from the surplus LiSO2 packs was due
to a near-total depletion of the sources a few years ago. The few that
remained for sale were priced at over $100 per pack. So if you have some
intact packs left, you might consider listing 'em on E&^y - after converting
to Li-ion, o'course. And I gotta tell ya, payload prep is FAR simpler now -
just plug the pack into a cell-balancing charger, tweak the beacon message,
test it and ship it!

Hi Harry,

I use a 3-cell pack of CR123 LiSO2 cells for our cutdowns. But the
cutdown controller activates the burners for just 10 sec, and I can
get 10 shots out a pack before the preflight short-circuit test yields
under 10 amps (my ad hoc test criterion). However, now that we're using
the load-sensing fast release, we've only used the burners once or twice
in order to keep the landing out of some nasty territory - like DIA. The
only load they see that test and a 12V brake lamp used to verify cutdown
functionality preflight.

The CR123's never even get warm to the touch during burns.

I have four packages of batteries left, still in their cardboard box and plastic bag. They are labeled at part number BA-5598/U and contain the 2/3rd size "D" cells. I use rechargables now and won't be using those btteries, if anyone is interested.

I know the smell of those batteries. It has a very dry feeling.

Hi Mike,

The battery I used that vented was the 2CR5. I have not used it since. I went with 2 Eveready alkaline 9v's and use them only once for a 10 sec burn. Haven't had any problems. All batteries/packs in my capsules are made up of the same 9v's and they have performed very well.

Hi Paul,

I got the 18650 Li-ion cells used in our payloads and a balancing
charger for 'em online from All Battery (www.allbattery.com).

Be careful "re-purposing" those batteries if they don't incorporate
protection circuits! Which all battery sells cheap as well.

6679. 18650 battery holders

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-06 14:27:44 UTC
From: Mark Conner
Topic: 6679 Message: 6679

The recent discussion on batteries prompted me to take a peek at eBay again
for 18650 Li-ion cells and battery holders. I found a couple of new sources
that might be of interest:

18650 battery holder (1S1P):
http://dkc3.digikey.com/PDF/US2010/P2473.pdf ($2.56 ea)

18650 battery holders with protection circuitry:
http://www.batteryspace.com/Li-Ion-18650-cell-series-Battery-Holders-with-PCB-installed.as
px
($10-20)

eBay has several sellers of Li-ion cells (some indicating protection
circuits built into the cell) for around $2-3/cell. Don't know particulars
on the brands, some are probably "off".

Hi

I'm flying a UV filter on the still camera for our next flight, primarily to prevent the camera filling with dirt when it lands. This leaves me with a lens ring that's just beggin' to have something else screwed onto it. This led me to think "Hmmm, I wonder how a polarizing filter would work up there?". Anyone ever use one? I wonder what the correct orientation would be? Our first light is planned for May 8 so time's runnin' out.

Thanks

The sky will be darker 90 degrees from the sun, if the filter is aligned correctly. The sky in near space won't be any different, but the earth could be. No matter how you align the filter, it will work well in one quadrant and not well in the other.

Can you send two cameras?

Hi Paul

Ok, that makes sense. My hope was that it might reduce some of the atmospheric reflections and improve the clarity of the ground below.

Right now we're limited to one camera. If it works, I may look at adding another. Were you thinking of two with different orientations on the filter or one with a filter and one without?

Thanks

Bruce

I wear presciption polarized sun glasses outdoors. They really do help reduce the glare off things like water. I would suggest looking thur the filter while viewing something outdoors and rotating the filter to get the best contrast. Then mount it on the camera with the same orientation. Jim Hannon

I'd be more concerned with condensation than dirt.

we have flown at least 30 flights with cameras, and not once has dirt
been a problem.

But condensation IS a major problem, where the flights we used windows,
50% of the images were fogged over. where as without the windows, the
only fogging we have had was after pop and the cold lens hit warm moist
air, but that stays fogged only for 5 minutes or so.

but with the windows, we never use them anymore.

If you want to penetrate the atmosphere you need a IR pass filter and
block most of everything else. that cuts through the blue haze pretty well.

I was thinking about two cameras with filters aligned 90 degrees apart.
That way one of them is bound to get a good picture. The effect should be
greatest in the morning (as opposed to noon) when the sun is at a low angle.

SigHi Joe

Ya, I was wondering about condensation too. I'll have to take a long look at things before I decide what to do.

Thanks

I'd be more concerned with condensation than dirt.

we have flown at least 30 flights with cameras, and not once has dirt been a problem.

But condensation IS a major problem, where the flights we used windows, 50% of the images were fogged over. where as without the windows, the only fogging we have had was after pop and the cold lens hit warm moist air, but that stays fogged only for 5 minutes or so.

but with the windows, we never use them anymore.

You might be able to do a dry Nitrogen (or Helium?) flush before attaching the filter. That may help. Maybe.

Also, note that a lot of modern digital cameras have infrared blocking filters built in (to avoid some weird colour shifts when photographing objects which have a lot of infrared light being produced/reflected). Thus, you may want to take a look at removing those before attaching an infrared only (e.g., visible blocking) filter.

Me say yes,

But claim no responsibility as to the statements below

we have been using H2 for over 20 years, and the tanks have been
transported in everything from the back end of pick up trucks with
NOTHING holding them, to in the trunks of cars, the back ends of ford
escort station wagon, the back seat of a chevy corsica,and lately the
back seat of a dodge neon.

geeech the stuff is NOT a bomb!

Keith,
The transportation issue is not so much the type of gas as it is the compressed gas cylinder. The danger comes from having the valve broken off of the end of the cylinder. The regulations prefer upright orientation, and want at least at 30 degrees above the horizontal. I have transported cylinders horizontally, but never outside the vehicle. My concern with the rear hitch shelf being behind the vehicle would be in a rear end collision that could launch the tanks horizontally. Always keep the protective cap secured.
Here's a story from Oklahoma State about a cracked valve:
http://ehs.okstate.edu/MODULES/cylinder/Theone_story.htm

and the Mythbusters video: http://www.youtube.com/watch?v=ejEJGNLTo84&feature=related
I agree with Joe that hydrogen is not the issue.

Pretty much standard for 18650 Li-ion cells: 2600 mAH and 3.7V nominal during discharge (4.2V max @ full charge, no load; 2.5 V min permissible discharge). I strap 2 in parallel to boost mAH rating w/ no problem. 18650's are commonly used in laptop battery packs, and are the most widely used size.

Another great place to get both prismatic LiPo and cylindrical Li-Ion battery packs, inexpensive smart CC-CV chargers, protection PCB's, and everything else you could need is http://www.batteryspace.com . I've purchased packs from them before (for a work-related project), and I'm going to use one of their packs very soon for a client of mine.

When I lived in Berkeley back in the 80's....a friend of mine took me down to the shipyards in Oakland one night and showed me what he did for fun....he grabbed nitrogen cylinders that still had some pressure in them, rolled them down to the edge of the water and laid them flat in the water with valve end sitting on the beach....he removed the protective cap and then hit the valve with a sledge hammer...<whoooooosh>...the cyinder would zip across San Francisco Bay just like a torpedo and probably went a mile or more out to sea.

Once in the chemistry lab, we had a cylinder fall over that was connected to a gas chromatograph and it's valve got knocked off during the fall when it hit a lab bench...it wasn't strapped to anything....it went through two walls before coming to rest.

When I signed up for metal shop in High School, we toured the shop area. The teacher pointed out a big patch in the corrugated metal roof above the welding stations. Somehow the one of the cylinders was knocked over during horse play, the valve busted off and it flew like a rocket through the roof and landed in the field next to the armory / National Guard station about 1/4 mile away. 30 something years later, I have never dropped a bottle, and I am still very careful when moving my gas welding tanks around...

Also, never transport the hydrogen, oxygen or other flammable bottles in your car trunk. If you must do so, at least leave the trunk open a bit. The problem is leakage. If by chance the valve did not seat properly and the flammable gas leaks out, builds up in that enclosed compartment, a single spark, static or otherwise can really ruin your day. Bottles should be transported according to the regulations, and with flammable gasses, assure that the gasses can escape safely away. Do a search on welding [bottle,tank,cylinder] explosions and you will see where somebody's day was ruined.

The 18650's are bigger than AA's - they're 18mm diameter and 65mm
long (that's where "18650" comes from). And since they run over 2x
the voltage of an alkaline, that's a good thing.

Check www.all-battery.com for some good prices on cells and protection
circuits. All the EOSS payloads have run on them for over 2 years.

This'll take you right there:
http://www.all-battery.com/li-polifepcm.aspx

Walgreens has 'em at a pretty good price:
http://tinyurl.com/ya5drm9

So, I've always read that you want to use these disposable lithium batteries in low-temperature environments, rather than rechargeables. Energy density is pretty high, they're good to -60C, and they're extremely reliable. Do you guys ever have problems running cobalt-based lithium-ion rechargeables? I know they're not very tolerant of low temps at all, but if they're insulated, I'm sure things could be just fine.

wow Mike

crazy minds think alike!

I have in my hands 4 of those exact same cells! the ones with the short wire tabs on each end. Black on one end and red on the other.

Now if I was to connect them all in series, is my initial thought to power a Micro track 300 and GPS unit.

What kinds of configurations have you guys made with these cells, what kinds of Ah capacities? etc.

What did you make to charge them with?

Joe

From: Mike Manes
Topic: 6696 Message: 6700

Walgreens sells Li-Fe primary cells that run about 1.5 V and come in
the AA format. They're great for balloon payloads, but kinda pricey.

Li-ion rechargeable cells run over 2x the cell voltage of alkalines and
Li-Fe and won't fit in AA holders - a good thing! But Li-ion does get
puny below -20C, unlike LiSO2 primary cells, like CR123's and the stock
surplus cells we used to get cheap, which are good to -40C. But I've yet
to hear of any battery chemistry that's good to -60C.

Do you mean Li-ion 18650's? If so, then a 4S config will get you 14.8V nominal - a tad high for any GPS I've worked with. I do use 4S with a switching buck regulator for the PC Electronics KPA-5 70 cm ATV xmtr in our video payload, however.

Each payload uses a different configuration. The AE0SS DF/cutdown beacon uses a 2P of 18650's for the Alinco DJ-C1 radio, and I stack a CR123 on top of that to feed a 5V LDO linear regulator for the PICAXE-14 uP and DTMF decoder. The 2P config yields 5200 mAH - enough to run the beacon for 2 days in the event of a rough recovery site.

I use a 1 to 4 cell Li-ion/Li-Po balancing charger from All Battery and charge the 18650s at 600 mA per cell (1200 mA for a 2P configuration).

You can get Li-ion rechargeable cells in an AA form factor. Not sure
they're the most efficient by volume or weight, but you can use standard AA
battery holders. Just don't accidentally pop them into consumer products.

I did find that Digi-Key now carries 18650 cell holders, which is a
relatively new product for them.

AA Li-ions:

http://www.batteryspace.com/li-ion14500cylindricalrechargeablecell37v750mahaasize277wh-ullisted.aspx

Not true button-tops, though, so may not work in all battery holders.

18650 holder:
http://search.digikey.com/scripts/DkSearch/dksus.dll?Cat=393250&k=18650

OK - so that's the 14500 (14mm D x 50 mm L) cell. But it's only
750 mAH - better'n most NiMH that size, and 3x the voltage, however.
Thanks for the links.

Wow pretty high current.

Being on the cheap Poverty side here, 4 in series as you say is like
14.8 perfect for a flight voltage.

Charging, hmmm, what ya think,, I have a bunch of Yaesu NC-60B
chargers. it's a HT charger,output measures 15.1 volts. under no load,
but it's label says output is 15 volts at 200 milliamps. It's quite
heavy and large for it's claim of power, so i'm wondering if it has a
regulator in it too?

Cuz like i said under no load I'm measureing 15.1 volts. yet it's
labeled output is 15 volts at 200 milliamps,, I wonder how well this
may charge that pack if left in a series situation. hmmmmm?

6707. Re: [GPSL] Lithium AA cells?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-09 04:37:17 UTC
From: Mike Manes
Topic: 6696 Message: 6707

Hi Joe,

Well, at full charge, Li-ions deliver 4.2V, so that 4S pack
delivers 16.8V - which could pop some 16V electrolytics, amongst
other stuff. The switcher clamps the Vcc to the xmtr to +12.5V.

Tenergy sez it's OK to charge at up to the 1 hr rate, or 2.6A per
cell, but that does make for some heat, so I ease back and use more
like a 4 hr rate, since I'm not in a hurry.

The recommended charge profile for Li-ion is constant current until
the cell voltage hits 4.2 V, and then hold 4.2 V constant until the
current drops under the 100 hr rate, or 26 mA per cell. One could
set up a lab DC supply with adjustable current limit to do that.
If you do charge faster, the cell temperature should be monitored
to keep it under 50C. My charger doesn't monitor temperature, however.

Mischarging Li-ions can be expensive and dangerous, so it's important
to get a charger that does the job right. It's a proper investment,
IMHO.

In Ohio, I can get Lithium AA and AAA at WalMart or Walgreens for a good price.

Joe...The Eveready L91 lithium batteries are usually available at the following: RadioShack, Walmart, Lowes, Batteries Plus and Walgreens.

Best pricing for an 8 pack:

Walgreens - sometimes as low as $16 a pack but usually $18 or so.
Lowes - usually around $18 to $19
Walmart - usually around $19 but hard to find since the meth labs use these and Walmart is their purchase point of choice.
Radio Shack - usually around $21
Batteries Plus - about $22

Some stores (particularly Walmart) will only sell your two 8-packs at a time to keep the meth labs at bay....they use the lithium strips inside as a catalyst.

6710. Streaming video from this Saturday morning UAH balloonsat flights

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-10 01:18:19 UTC
From: wb8elk@aol.com
Topic: 6710 Message: 6710

Upwards of 5 balloons possible from Huntsville, AL....look for APRS callsigns starting with KG4WSV, WB8ELK and UAH on 144.39 (as well as 144.34 and 144.36

Streaming video of the launches are possible at the following website:

http://www.batc.tv

Click on "Members Streams"

Then click on "WB8ELK" and hit View Stream

6711. Live Stream for EOSS-150 on 4/10

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-10 02:34:22 UTC
From: Rick von Glahn
Topic: 6711 Message: 6711

EOSS-150 will be launching at 7am MDT (13:00 UTC). We've got some guys working up a live broadcast capability. The stream is available at:

eoss.tv

or you could go into the eoss website to the page via this url:

www.eoss.org/live/index.htm

The first is a bit easier to remember.

Current flight announcement data is at:

http://www.eoss.org/flight

and the prediction is at:

http://www.eoss.org/flight/prediction.htm

If you are sort of near Denver (like within 400 miles) I run predictions for many locations outside of the immediate flight area. Look at:

http://www.eoss.org/flight/distant_observers.htm

And see if your general area is covered. Not much info available but, the time the balloon rises above your local horizon is listed along with the azimuth of the bearing to the balloon as well as distance and the altitude of the balloon at that time. Also listed, max elevation for your site and the set time of the balloon.

It's our 150th flight WOW, it has been a really fun 20 year run at EOSS!!!

73 -- Rick, N0KKZ

Congratulations Rick & all @EOSS . . . 20 years, eh ? 150 launches !

I remember how I hated to leave Denver just before that first launch,
after spending so much time with the group getting it ready.
Tell everyone I said Howdy ! Most of em probably say "Um, who ??"
(surely some of the original group is still there)

Funny how, 20 years later - I've run into Billy.Brown again and get to
participate in his balloonacy. I've setup a temporary IGate tonite
as they have so many launching tomorrow, some will be on 144.36 ...

73 for now - and happy EOSS'ing /;^)

6713. Lithium AA batteries on sale

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-10 08:24:24 UTC
From: wb8elk@aol.com
Topic: 6713 Message: 6713

Just visited Walgreen's....they have a sale (until 4/24 I think) on the L91 Eveready AA Lithium cells I use on most flights.

$2 off the 8-pack (price after discount $18)

But here's the real deal:

$2 off the 4-pack (price after discount $8)...so 8 batteries bought as two 4-packs equals $16, which is usually the rock bottom price you'll find on these.

For comparison...the 4-pack at Rite Aid is $10.99.

- Bill WB8ELK

You won't find any at the Madison AL Walgreens though....I bought them all.

I frankly don't know how good a price this place has...

http://www.batteryspace.com/search.aspx?find=&log=false&category=992

But they murder the price of Li 123 cells I use in some high powered flashlights. Price is dependent on quantity purchased but even the worst deal was better than anything on Amazon last time I checked.

Worth a peek.

They carry an off brand for 1/2 price of energizers (more or less) they spec at a slightly shorter runtime but they are slightly lower voltage and mAh (1.5V 2900mAh vs Energizer's 1.72V 3000mAh). Might be a good test candidate if the voltage isn't a concern.

Joe...usually they would fail at 60,000 feet for the many manufacturers who interpret the DoD incorrectly. The Copernicus will fail at 27,000 feet unless set to AIR mode....some cheap units fail even lower due to not allocating enough altitude digits....so they fail at 10000 meters....I've seen this on one brand a few years ago.

The "anti-scud" rule kicks in above about 62K', but it's not supposed to apply unless the speed is also > Mach 1. Some GPS's top out at 20 km (about 100K' and others at 30 km (about 130k'). Then some intended for terrestrial use kick out at 18K'. Finally, many GPSs will die if you let 'em get too cold.

Hi Joe,

As Bill noted, some just don't provide enough digits in their
GGA sentences to go any higher, or they just truncate altitude
computation above some arbitrary figure.

Ralph W0RPK used to have a nice listing of the capabilities of a number
of different GPS engines on his web site before he retired, but I
can't find it any more. Maybe someone imported it before he retired?

Congrats to EOSS on their 150th....I still remember EOSS-1 and the WVN flights prior to that like it was yesterday. I particularly enjoyed listening to the 10 meter beacon sending the temperature from Colorado to NH on one of those first flights. I still have the ear of corn from the payload I dropped into the only corn field in Colorado during your early 90's balloon conference.

Yeah? Well, that was back when you had hair, too, Jackson. :=).

Been a great run, Jack, and we all owe you a debt of gratitude
for taking the initiative to create EOSS and get it running like
a top!

I propose that we send Jack one of those pins that we hauled up
today.

6729. ARHAB launch announce - RoboMo & NAREA

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-11 13:06:48 UTC
From: ccccrnr@aim.com
Topic: 6729 Message: 6729

What is the typical process for announcing a balloon to get it listed on the website and qualify for any records if it sets any?

the RoboMo and NAREA groups of St Louis area want to schedule a 1st untethered balloon launch for either group.

May 1st 2010 from Winfield, MO to land in IL pending good enough weather of <10mph wind and clear visibility
back up date would be May 22, 2010 at this point

Thanks,
Carlton Corbitt

Posting announcements to the Yahoo "Balloon_Sked" list is preferred. You should also go to http://www.arhab.org and fill out the form at the "Submit launch information" link.

"qualify for any records if it sets any"?

Great question here. I'm really new and ignorant on this APRS stuff. If I were to receive APRS data, What exactly do I submit for the records? With findu.com I would assume all information could be had using this site. How can one tell that I received data directly and not by using Findu.com? So far I have been using a video camera to watch the realtime data (just in case) to confirm any contacts. Any help would be appriciated.

Hi Bill,

Yeah, those were the days when we had to DF triangulate to get a fix.
And when we learned that 10m doesn't propagate over the ground worth
a hoot - we had to use Air One to find it out east. GPS and APRS
make the T&R job comparatively trivial nowadays.

And EOSS-1 actually was WVN-1 - we kinda decided to highjack it, since
it was the same group that became EOSS shortly afterwards.

That conference that coincided with EOSS-13 and your 'ELK-gazillion?
took an enormous amount of work to put together, what with publishing
a proceedings and all. It was attended by guys from Winzen and Kaysam,
IIRC, and there was one of Bob Bruninga's first papers on ARPS in there
as well. I think that was one of the first flights of our cross-band
repeater as well, when we learned that it's a bad idea to leave the 70 cm
uplink rcvr squelch open, since that made the 2m downlink real hard to DF on.

6736. How To Manual

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-12 16:08:54 UTC
From: Keith Kaiser
Topic: 6736 Message: 6736

I've been contacted by a local high school here in the KC area looking to set up their own ARHAB program. Does anyone have a picture of the equipment requirements for such a thing? What I'm thinking about is a simple guide to hooking everything together, for example;

1) The balloon systems... i.e. balloon, parachute, etc.
2) Nearsat system... i.e. 2m handheld, TNC, batteries, camera, etc.
3) Tracking system... i.e. receiver, TNC, computer etc.
4) Software systems... i.e. Xastir, UIview, etc.

I know I've seen a really good write up by someone somewhere but I can't remember where or find it via Google. So if you have something these guys might be able to use please point me at it.

Thanks...

I would suggest that the payload came from the TU HARP flight last October that experienced pre-burst chaos. It was in that general area when the chaos caused payload separation.

At 10 mB, it will get you to 100,000 feet. It's also surface mount, so get
a PCB breakout or make your own.

From: natewac@aol.com
Topic: 6744 Message: 6744

I submitted this the other day without a reply. Hopefully someone will be able to answer this for me.

I'm really new on APRS. My intention is to try to make the record books via APRS Data receipting. If I were to receive APRS data, What exactly do I submit for the records in order for the receiption to be recognized? With Findu.com I would assume all information could be had using this site. How can one tell that I received data directly from the balloon and not by using Findu.com? Does received APRS data have more information than what Findu.com shows? Again I'm new with APRS. So far I have been using a video camera to record the realtime data (just in case) to confirm any receiption. Any help would be appriciated.

Tony,

The problem isn't that you asked a question but the question itself. Few if any "records" are kept on or about just receiving a signal. Most if not all are based on a two-way conversation or exchange of information. For example because of a balloon launched in Missouri, a station in Texas was able through the onboard repeater cary on a conversation or an exchange of information with another station in Michigan. In the 2m band this would not normally be possible and even through a high altitude balloon is very uncommon. So a record of this might be considered.

But I do not currently maintain any "records" of receipt of a signal. However it may be of interest to the ARHAB community to hear about your receipt so by all means tell us about it on this forum.

You and i have discussed this before and as you know I keep the records for the ARHAB community. I can't think off-hand how I would ask for proof of this kind of "new" record to be kept.

Keith,

I think Nate is looking for the proof standards for the "*Greatest Telemetry Downlink Reception Range" record category. See about halfway down on http://www.arhab.org/ARHABrecords.htm.*

In the past, Ralph W0RPK has accept e-mail copies of the log data generated by the APRS program or TNC capture, along with a statement of the sender where the receiving equipment was located (lat/lon). The APRS data would contain the balloon's location, and from that he could generate a great-circle distance and thus track records for telemetry reception.

In theory, there is nothing to prevent total fabrication of a record claim for APRS data reception - even with TNC time hacks, etc., that could be fabricated by hand. Simple checks would prevent implausibly long records from being claimed though.

Mark, You hit the nail on the head "(In theory, there is nothing to prevent total fabrication of a record claim for APRS data reception)". Since I'm brand new using APRS I've only tried to receive just a couple of balloons. As I watched them on Findu.com I asked myself "What more information is needed to be submitted than what is on Findu"? This is the reasoning of video recording my realtime receiption. I guess to post on Youtube for proof of receiption. And I'm not sure if this would even be good enough. Any thoughts from you guys......

Hi Keith and Nate....I would think that's what Nate is referring to.... but the APRS reception would have to be a communications received DIRECTLY by the station sending in the record...not via a digipeater hop....you can tell that by looking at the APRS header to make sure there are no digipeater callsigns in the header.....the record of 478 miles that I have listed in that category was based on a clear channel 144.34 MHz reception of APRS from a balloon over Findlay, Ohio as received here in Alabama....so no digipeaters were involved on that frequency. It could be a difficult feat to set a record on 144.39 by trying to filter out the direct signal from the digipeated ones. I'd advise Nate to try for the Greatest Telemetry Downlink Reception Range record by receiving either balloon APRS signals when sent on something other than 144.39...or by receiving one of the multi-mode digital signals (such as DominoEX) like I send on 144.36 or 144.34 from here....going to have another one going up this Sunday morning on 144.34 if you want to try for that one Nate....use FLdigi to decode it on DominoEX22.

Bill, Thanks for the reply. I understand the balloon would have to be heard directly and not via digipeater. Lets say your balloon goes up this Sunday. And it's being tracked on Findu.com. Even though I can't hear it, And even though it's wrong I submit the long,lat and balloon higth that I see from Findu.com just to get in the record books. I would never do this...but it would be possible to buffalo someone wouldn't it? Don't get me wrong I think tracking the balloon using Findu.com is a very important tool. I'm just wondering how one would know if the data was received directly or via Findu?

Nate you were going to try and track w0nsv-11 this past Sunday, did you hear it? I was on 144.39Mhz a non-traditional APRS frequency however I was also iGating it into the findu system via Xastir and a high-speed Verizon dongle.

We launched at exactly 8:40am.

Tony,
Bill's new telemetry sender is using a format that does not decode
and automatically appear on FindU or any of the APRS-IS sites.

If you download the dl-fldigi program, and receive the packets they will
be sent over your internet conenction to a collection site, and published.
This is different than the typical APRS telemetry mode, no digipeaters.
Reporting in this fashion would readily confirm your direct reception.

I don't have all the details with me at work, but I'd be happy to share
the links and setup tips once I get home this evening. I was only
introduced to the dl-fldigi program last week, but it worked great for me.
It uses the soundcard of your PC for the modem - headphone jack out of
the radio into the mic input of the laptop/desktop ... pretty simple.

73 for now /;^)

Hi Nate,

You can tell whether it's from Findu, digipeated or direct by looking at the header field before the data portion of the packet. I'm not at a computer where I can send you the detailed info in that regards....a search on APRS on Google might get you that info.

Bill, Thanks for the reply. I understand the balloon would have to be heard directly and not via digipeater. Lets say your balloon goes up this Sunday. And it's being tracked on Findu.com. Even though I can't hear it, And even though it's wrong I submit the long,lat and balloon higth that I see from Findu.com just to get in the record books. I would never do this...but it would be possible to buffalo someone wouldn't it? Don't get me wrong I think tracking the balloon using Findu.com is a very important tool. I'm just wondering how one would know if the data was received directly or via Findu?

Hi Keith and Nate....I would think that's what Nate is referring to.... but the APRS reception would have to be a communications received DIRECTLY by the station sending in the record...not via a digipeater hop....you can tell that by looking at the APRS header to make sure there are no digipeater callsigns in the header.....the record of 478 miles that I have listed in that category was based on a clear channel 144.34 MHz reception of APRS from a balloon over Findlay, Ohio as received here in Alabama....so no digipeaters were involved on that frequency. It could be a difficult feat to set a record on 144.39 by trying to filter out the direct signal from the digipeated ones. I'd advise Nate to try for the Greatest Telemetry Downlink Reception Range record by receiving either balloon APRS signals when sent on something other than 144.39...or by receiving one of the multi-mode digital signals (such as DominoEX) like I send on 144.36 or 144.34 from here....going to have another one going up this Sunday morning on 144.34 if you want to try for that one Nate....use FLdigi to decode it on DominoEX22.

Keith,

I think Nate is looking for the proof standards for the "Greatest Telemetry Downlink Reception Range" record category. See about halfway down on http://www.arhab.org/ARHABrecords.htm.

In the past, Ralph W0RPK has accept e-mail copies of the log data generated by the APRS program or TNC capture, along with a statement of the sender where the receiving equipment was located (lat/lon). The APRS data would contain the balloon's location, and from that he could generate a great-circle distance and thus track records for telemetry reception.

In theory, there is nothing to prevent total fabrication of a record claim for APRS data reception - even with TNC time hacks, etc., that could be fabricated by hand. Simple checks would prevent implausibly long records from being claimed though.

No I didn't her it. I stopped trying around 60,000 ft. I did however start hearing the W3EAX-11 (Maryland) balloon at around 79,000 ft. It popped about 83,000 but before it was strong enough to gather data. I'm was told the transmitter was about 300 milliwatts. When at 80,000 ft the balloon was about 358 miles from my QTH.

Nate you were going to try and track w0nsv-11 this past Sunday, did you hear it? I was on 144.39Mhz a non-traditional APRS frequency however I was also iGating it into the findu system via Xastir and a high-speed Verizon dongle.

We launched at exactly 8:40am.

I appreciate the offer. I have Fldigi but unfortunately the computer that's in does not have Internet access. I've been using it about 3 weeks now. It is a very good program. And I'm sure I'm not using it to it's full potential. Thanks agin.

Tony,
Bill's new telemetry sender is using a format that does not decode
and automatically appear on FindU or any of the APRS-IS sites.

If you download the dl-fldigi program, and receive the packets they will
be sent over your internet conenction to a collection site, and published.
This is different than the typical APRS telemetry mode, no digipeaters.
Reporting in this fashion would readily confirm your direct reception.

I don't have all the details with me at work, but I'd be happy to share
the links and setup tips once I get home this evening. I was only
introduced to the dl-fldigi program last week, but it worked great for me.
It uses the soundcard of your PC for the modem - headphone jack out of
the radio into the mic input of the laptop/desktop ... pretty simple.

73 for now /;^)

Tony,
Personally, I believe that the foundation of all of the ARHAB records follows from the principle of being trustworthy. All of amateur radio actually is based on this principle. It is almost impossible to have foolproof verification. I know that when you worked the crossband repeater on our BASE 39 flight last summer, the record verification depended on your word of honor and that of the NØUOE.
Certainly, any distance much greater than the anticipated line of sight radio horizon would be viewed skeptically. Of course, if there were favorable skipping conditions, then a forgery at long distance might also be accepted.
Howard, KC9QBN
P.S. - I'm planning on trying to float the crossband repeater again this year from the SpaceJam 4 event at Rantoul, IL on August 7. If we get lucky, maybe you and Keith, WA0TJT could make contact. That would be an EBE event at about 600 miles.

Bill, Thanks for the reply. I understand the balloon would have to be heard directly and not via digipeater. Lets say your balloon goes up this Sunday. And it's being tracked on Findu.com. Even though I can't hear it, And even though it's wrong I submit the long,lat and balloon higth that I see from Findu.com just to get in the record books. I would never do this...but it would be possible to buffalo someone wouldn't it? Don't get me wrong I think tracking the balloon using Findu.com is a very important tool. I'm just wondering how one would know if the data was received directly or via Findu?

Hi Keith and Nate....I would think that's what Nate is referring to.... but the APRS reception would have to be a communications received DIRECTLY by the station sending in the record...not via a digipeater hop....you can tell that by looking at the APRS header to make sure there are no digipeater callsigns in the header.....the record of 478 miles that I have listed in that category was based on a clear channel 144.34 MHz reception of APRS from a balloon over Findlay, Ohio as received here in Alabama....so no digipeaters were involved on that frequency. It could be a difficult feat to set a record on 144.39 by trying to filter out the direct signal from the digipeated ones. I'd advise Nate to try for

the Greatest Telemetry Downlink Reception Range record by receiving either balloon APRS signals when sent on something other than 144.39...or by receiving one of the multi-mode digital signals (such as DominoEX) like I send on 144.36 or 144.34 from here....going to have another one going up this Sunday morning on 144.34 if you want to try for that one Nate....use FLdigi to decode it on DominoEX22.

Keith,

I think Nate is looking for the proof standards for the "Greatest Telemetry Downlink Reception Range" record category. See about halfway down on http://www.arhab. org/ARHABrecords .htm.

In the past, Ralph W0RPK has accept e-mail copies of the log data generated by the APRS program or TNC capture, along with a statement of the sender where the receiving equipment was located (lat/lon). The APRS data would contain the balloon's location, and from that he could generate a great-circle distance and thus track records for telemetry reception.

In theory, there is nothing to prevent total fabrication of a record claim for APRS data reception - even with TNC time hacks, etc., that could be fabricated by hand. Simple checks would prevent implausibly long records from being claimed though.

I'll be flying the same system as last summer, uplink on 144.36HHz downlink on 446.025 MHz. It is a unit that I borrow from Jeff Dailey that he built. I don't have any equipment specifics.

Keith,

I think Nate is looking for the proof standards for the "Greatest Telemetry Downlink Reception Range" record category. See about halfway down on http://www.arhab. org/ARHABrecords .htm.

In the past, Ralph W0RPK has accept e-mail copies of the log data generated by the APRS program or TNC capture, along with a statement of the sender where the receiving equipment was located (lat/lon). The APRS data would contain the balloon's location, and from that he could generate a great-circle distance and thus track records for telemetry reception.

In theory, there is nothing to prevent total fabrication of a record claim for APRS data reception - even with TNC time hacks, etc., that could be fabricated by hand. Simple checks would prevent implausibly long records from being claimed though.

Howard,

"any distance much greater than the anticipated line of sight radio horizon would be viewed skeptically." To be honest with you this statement is the reason why I brought up this subject. I saw some of the data reception records have been held for many years. With the antennas that have (4x13b2's=52 elements vertical) I would think that I have a good chance of getting a high ranking at some point in time. I've always played by the rules and I just didn't want someone to think that cheating took place. After all it does look easy for one to manipulate the system. Not that anyone would...but we have all seen stranger things.

As for SpaceJam 4.......I would love to give that a shot! Please keep us in mind as the time gets closer. Thanks for the thought.

Hi Keith and Nate....I would think that's what Nate is referring to.... but the APRS reception would have to be a communications received DIRECTLY by the station sending in the record...not via a digipeater hop....you can tell that by looking at the APRS header to make sure there are no digipeater callsigns in the header.....the record of 478 miles that I have listed in that category was based on a clear channel 144.34 MHz reception of APRS from a balloon over Findlay, Ohio as received here in Alabama....so no digipeaters were involved on that frequency. It could be a difficult feat to set a record on 144.39 by trying to filter out the direct signal from the digipeated ones. I'd advise Nate to try for the Greatest Telemetry Downlink Reception Range record by receiving either balloon APRS signals when sent on something other than 144.39...or by receiving one of the multi-mode digital signals (such as DominoEX) like I send on 144.36 or 144.34 from here....going to have another one going up this Sunday morning on 144.34 if you want to try for that one Nate....use FLdigi to decode it on DominoEX22.

Subject: Re: [GPSL] APRS Data receipting

Keith,

I think Nate is looking for the proof standards for the "Greatest Telemetry Downlink Reception Range" record category. See about halfway down on http://www.arhab. org/ARHABrecords .htm.

In the past, Ralph W0RPK has accept e-mail copies of the log data generated by the APRS program or TNC capture, along with a statement of the sender where the receiving equipment was located (lat/lon). The APRS data would contain the balloon's location, and from that he could generate a great-circle distance and thus track records for telemetry reception.

In theory, there is nothing to prevent total fabrication of a record claim for APRS data reception - even with TNC time hacks, etc., that could be fabricated by hand. Simple checks would prevent implausibly long records from being claimed though.

Tony,

The problem isn't that you asked a question but the question itself. Few if any "records" are kept on or about just receiving a signal. Most if not all are based on a two-way conversation or exchange of information. For example because of a balloon launched in Missouri, a station in Texas was able through the onboard repeater cary on a conversation or an exchange of information with another station in Michigan. In the 2m band this would not normally be possible and even through a high altitude balloon is very uncommon. So a record of this might be considered.

But I do not currently maintain any "records" of receipt of a signal. However it may be of interest to the ARHAB community to hear about your receipt so by all means tell us about it on this forum.

You and i have discussed this before and as you know I keep the records for the ARHAB community. I can't think off-hand how I would ask for proof of this kind of "new" record to be kept.

On Apr 13, 2010, at 2:41 PM, natewac@aol. com wrote:

I submitted this the other day without a reply. Hopefully someone will be able to answer this for me.

I'm really new on APRS. My intention is to try to make the record books via APRS Data receipting. If I were to receive APRS data, What exactly do I submit for the records in order for the receiption to be recognized? With Findu.com I would assume all information could be had using this site. How can one tell that I received data directly from the balloon and not by using Findu.com? Does received APRS data have more information than what Findu.com shows? Again I'm new with APRS. So far I have been using a video camera to record the realtime data (just in case) to confirm any receiption. Any help would be appriciated.

A question fort ya all.

Of course we all or i think we all have used shroud rings on out round parachutes.

to help the chute open as fast as possible, and to help keep the lines from tangling.

But some of these new fangled chutes, have any of you used them on your balloons. and did you also add a ring to them also?

That's all we've ever used, and no we don't use a ring. Ours have all come
from Rocket Man (http://www.the-rocketman.com/recovery.html).

The flancy one in the pix doesn't have an apex vent, and thus may oscillate badly at altitude. Unless you can steer one, a 'chute is just a utilitarian tool that's gotta work right every time.

I'm no expert on 'chute aerodynamics, but I believe the Rocket Man stuff is designed so that it spills out the sides. Notice how the main canopy is cut away between the shroud lines.

He also claims that fewer shroud lines means there's less chance of a tangle. That's probably more of a factor on a tumbling rocket, but I can say that we've NEVER had to mess with lines when we're prepping for a launch.

Hi Zack,

Well, when the air bubble releases out from under the skirt, it's usually a bit asymmetric, and that jet creates a reaction force that tips the canopy in the opposite direction, thus enhancing the asymmetry until the high pressure bubble under the canopy is depleted enough to let the 'chute re-erect. In doing so, it overshoots a little, thus producing an asymmetric dump on the other side ... and so on.

That's the basic mechanism of parachute oscillation, and it's why apex vents were developed. That mechanism operates more violently at the higher true airspeeds that we encounter coming down from 100K', however. That's evident from the descent foto shown on the Rocketman "customers" web page.

I suspect that the 4-shroud scalloped skirt design does help the 'chute deploy from a packed state in a rocket, and that probably is also effective at altitude as well, thus minimizing the need for a spreader ring.

BTW, I >despise< the spreader ring, since it's the device that's responsible for the 'chute getting "Rubicked" due to a sloppy recovery. That happens when the canopy gets passed thru the spreader ring via some obscure pair of shrouds. Figuring out which pair that was is a real quiz - and guessing wrong just squares the quiz! In a couple of cases, I've had to remove the shrouds from the canopy and reassemble the whole shebang - not how I like to spend a whole afternoon :=(.

Anyway, if the Rocketman 'chute has a good record of reliable deployment at altitude, then the only thing it could use is an apex vent.

I use the SkyAngle 'chutes by B2. http://www.b2rocketry.com/ The SkyAngle chutes are similarly designed as what you have pictured.

Granted I've had only 5 HAB flights ut the 'chutes work just fine. I've had many dozens of high powered rocket flights with these 'chutes and they work well every time.

I like the simplicity. We don't use any ring. Our set-up is simply a line tied from the balloon nozzle to the loop on the SkyAngle 'chute (check to be sure what you purchase does have a loop) and then another line to the payload from the swivel at the bottom of the 'chute suspension lines.

Our most flown SkyAngle chute is a 52" for a 5 lb payload. No problems yet! But we do get rather quick returns after burst.

I've read about the oscillations that can occur. I can't find it now, but we were originally turned on to this design by a rocket enthusiast, and I'm guessing that he is the one that explained the theory.

Basically, instead of allowing that bubble of high pressure to build up until it spills off the side, the notches up the sides allow a more even venting. I suppose by being triangular shaped, a small amount of pressure can therefore be relieved with a very small amount of tippage...

Not sure if that's marketing BS or what, and I can't find it on their website. It's very possible that the guy that told me about them, read that in a magazine review or something. That was ~10 years ago, and I've slept since then.

One other thing that I can say is that he will sew the loop in the apex, ready for attaching a balloon. Rocket Man's chutes are very good quality - we have 3 and the oldest probably has 8-10 flights on it with zero damage.

WOW! I can't even think of how many times that has happened to me too.
I don't understand it either! No matter how carefully you fold the
chute, and wind up the lines, when you put it away for a while and
then take it out to get feady for a flight, you end up cutting all the
lines and start over because it Rubicked! awesome and perfect description!

The 4 line chute even has a ribic in one pair, of the lines and i have
yet to figure it out. and thats even without the schroud ring!

The Rocketman and B2 chutes do look pretty simple for launch prep. Prices are reasonable too. My primary chute is about 10 years old and after 30-some flights is about ready for a well-deserved retirement.

I agree with Zack that the notches in the skirts look like they would mitigate the oscillation. The proof would be in the flying - does anyone have any video from a descent showing how stable they are?

PERFECT!

That is exactly what I was looking for. and it easily made the decision
for me.

Shroud ring still, and added top vent holes.
I think the spilling in this chute was the oscillation seen.

Heres another thought i was thinking of. because the PBC seems soo
incredibly violent especially right at burst I wonder if the whole
system is getting yanked really hard at the time of explosion?

I wonder if the support line between the chute and balloon instead of
rope, if it was like latex sugical tubing. to act like a shock
absorber. I wonder if it would bake any diffference?

6773. Re: Chute line tangles

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-15 12:31:42 UTC
From: BASE
Topic: 6744 Message: 6773
Attachments: 1 described; binary payloads are missing from this source WARC

We avoid any chute line tangle problems with two zip ties. After recovery we make sure that the lines are not tangled. One zip tie is placed around all 8 lines at the chute and a second pulls the lines taut above the spreader ring. Only drawback would be if you forget to cut the ties before releasing on the next launch.
We have used chutes from spherachutes without any problems.

PERFECT!

That is exactly what I was looking for. and it easily made the
decision for me.

Shroud ring still, and added top vent holes.

I think the spilling in this chute was the oscillation seen.

Heres another thought i was thinking of. because the PBC seems soo
incredibly violent especially right at burst I wonder if the whole
system is getting yanked really hard at the time of explosion?

I wonder if the support line between the chute and balloon instead of
rope, if it was like latex sugical tubing. to act like a shock
absorber. I wonder if it would bake any diffference?

wrote:

The Rocketman and B2 chutes do look pretty simple for launch prep.
Prices are reasonable too. My primary chute is about 10 years old and
after 30-some flights is about ready for a well-deserved retirement.

I agree with Zack that the notches in the skirts look like they would
mitigate the oscillation. The proof would be in the flying - does
anyone have any video from a descent showing how stable they are?

I use the SkyAngle 'chutes by B2. http://www.b2rocketry.com/
The SkyAngle chutes are similarly designed as what you have pictured.

Granted I've had only 5 HAB flights ut the 'chutes work just fine.
I've had many dozens of high powered rocket flights with these 'chutes
and they work well every time.

I like the simplicity. We don't use any ring. Our set-up is simply a
line tied from the balloon nozzle to the loop on the SkyAngle 'chute
(check to be sure what you purchase does have a loop) and then another
line to the payload from the swivel at the bottom of the 'chute
suspension lines.

Our most flown SkyAngle chute is a 52" for a 5 lb payload. No problems
yet! But we do get rather quick returns after burst.

From: Alan Sieg WB5RMG
Topic: 6774 Message: 6775

> Do you have an idea what time Sunday your balloon may launch?

I'll try to fill-in, but Bill may have a better time frame.
Starting prep at 9am CDT, the first launch not likely before 9:30,
but hopefully no later than 10am. Half hour to 45 min to get the next
one ready, and again the next one. I'm not sure which flight tho will
have the Domino Tx... If you can follow the streaming video (assuming
that it will be active) that might be the best way to find out, real-time.
The live stream is found with http://batc.tv - click on 'Members',
then look for wb8elk near the bottom of the list. If it is active
you should have live video and audio, and an interactive keyboard chat.

The dl-fldigi is a custom binary, not the same as the one Dave - w1hkj
distributes via his web site. This is a simple stand-alone install,
and can be loaded onto any internet-connected PC. I have seen this
Domino work well just holding a handheld radio near the microphone
on a laptop.. very robust decoding under minimal signal conditions.

Quick instructions I got last week from M6JCX: (James Coxon)
- http://dl-fldigi.googlecode.com/files/dlfldigi-3.11.4r85-vista.zip
(the vista version is also for XP)
- Save to desktop even, run it, then go "Configure" menu -> Operator,
fill in your call sign and some details and then go to the DL Conf tab
and select bill's payload in the drop down box ...
- the final thing to check is in the misc tab of the configuration
in text capture 'enable detection and extraction' is to be ticked ...
- a good guide is here: http://projecthorus.org/?page_id=336

Once you hear telemetry and see WB8ELK telemetry string on your screen,
it should also be showing up on http://spacenear.us/tracker

I don't yet know if I will be at home, at church, or at the launch site..
Sometimes I don't receive my daily instructions until the sun comes up.
Enjoy /;^)

The trick to a Rubix-free recovery is to cinch up the shroud lines nice
and tight at the skirt, midway down towards the ring, right at the ring
and below the ring so the ring looks like a bike wheel. Then roll up
the 'chute and shrouds nice and tight like a bedroll that yer gonna
carry it on a 20-mile hike. It's stored and transported in a big
ol' leaf bag to keep it dry, clean and intact.

I use plastic "bread ties" intended for gardening use, and stow 'em on
the spreader ring during prelaunch prep for the T&R team to use on
recovery. Seems to work OK.

Shux - it's just getting broken in at 30 flights. We have one of the original 5 ft 'chutes still in use for exempt flights that prolly has 80 under its belt.

Getting shut of the shards ASAP after burst is probably the most
effective measure against PBC. Then it's up to the 'chute and
payload string dynamics. Best to put the "plumb bob" payload at
the bottom.

Hi Alan,

NASA Glenn is doing a BalloonSat school competition in late May...I plan to be there...Dave Snyder KB8PVR of that group is a member here on the GPSL list and will be talking at the BalloonSat Forum at the Dayton Hamvention about their program at NASA Glenn.

BTW...the BalloonSat Forum will be held Friday May 14th between 12:15 pm to 2:15 pm EDT at the Dayton Hamvention....we have quite a lineup of the early pioneers of ARHAB giving talks (a combined total of 100 years of ARHAB flights between us)....I will post the forum speakers list in the next email.

We plan to launch a balloon from the flea market at the Hamvention right after the Forum.

Hey all,
There is another good guide to setting up dl-fldigi on the ukhas wiki (
http://ukhas.org.uk/guides:tracking_guide) - some of the radio bit might be
a little basic but the rest is good!

Also if you add in your receiving station's latitude and longitude in dd.ddd
using + or - instead of NSEW (just a rough position) it'll plot your
position on to the map, would be good to get some feedback about at what
altitude you start hearing the balloon and whether the horizon circle is
appropriate (you'll see on the map what i mean!).

If all goes well the data received by dl-fldigi will be plotted onto
http://spacenear.us/tracker . Finally there is often conversation on the
#highaltitude channel on irc.freenode.net

Any questions get in touch.

James
M6JCX
http://www.pegasushabproject.org.uk

p.s. there is a UK balloon launch today at 09:00 UTC from Northern Ireland
which will be shown on the spacenear.us page - hopefully with some images as
well!

Plastic-coated wire ties also serve this duty for us, and they don't risk
cutting shroud lines on removal. During launch prep, we store 'em on the
spreader ring for use by the recovery team. And they're cheap and reusable.

6786. UAH Balloonsats to fly Sunday morning at 9 am CDT from Huntsville AL with streaming video

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-18 06:38:46 UTC
From: wb8elk@aol.com
Topic: 6786 Message: 6786

Three Balloons:

144.39:

Balloon 1: UAH-1 and WB8ELK-10
Balloon 2: UAH-2 and WB8ELK-11
Balloon 3: UAH-3

Also on Balloon 3: WB8ELK on 144.34 DominoEX22 and 300 baud 8-bit ASCII RTTY

Predicted landing site is 2 miles SW of Henagar, AL

Streaming video of Launch: http://www.batc.tv select "Members Streams" then select "WB8ELK" and hit "View Stream"

After the launches we will also be attempting a Moonbounce contact with Arecibo dish in the afternoon and may be streaming the video of that if my netbook's batteries hold up.

6787. HF balloon net

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-18 15:24:09 UTC
From: natewac@aol.com
Topic: 6787 Message: 6787

I was wondering if anyone has ever thought about communicating on an HF band while listening for the balloons while they're being launched and tracked? Kind of like an HF balloon net. Any thoughts?

We've used HF a few times, and it works on 40m once you get past the skip zone. However, with everything else going on during the chase, it's hard to listen to the noisy HF signals. I often found that I'd turn down the volume on the HF rig to make a VHF call, and forgetting to turn it back up.

My thinking was not for those involved in the chase or launch but or those who are listening for the balloon itself. It was just a thought. Thanks for the reply.

That's how it all was done before the days of the internet.

We had a weekly HF net where we would announce shed's of up coming flights, and such. As well a discuss playloads design. equipment etc. but then the net was pretty small too. maybe only what 6 groups were doing flights in those days? I ran the net. And it was a blast.

Then on flight days many many groups had HF stations at the launch sites so the rest of the world not local to the flight could at least know what's happening. And if the payload should have any HF trannies on board (and many did in those days) they would relay into the HF net what they may be hearing on HF.

But once the internet came to be. most of tye HF stuff faded away.

I know that there has been some discussion regarding our balloons on various nets that we (the chase team) haven't been directly involved in. I'm not sure what's being said on that (obviously), but I wouldn't think it would be too exciting since there wouldn't be any live updates. Plus, if there were a problem or change in schedule, they wouldn't necessarily know about it.

It seems like Pete (up in Salina) has used HF nets on a lot of his chases. Not totally sure to what capacity.

These guys,

http://www.all-battery.com/4pcstenergyli-ion1865037v2200mahbatterywithtabs.aspx

What are the symptoms of them being abused?

Heres the history.

I have a set of four in series that I made into a pack. From the factory they had a charge on them the level? who knows. But i tested them on a microtrac 300 and it lasted 11 hours when it got to the 12 volt suggested cut off point.

Ok, I don't have a real charger for them but i trickled them. with a yaesu HT charger that hs a output of 15.2 vdc and maz 200 miliamps.

it took a long time to get the pack back up to that level. I guess ideal max is 16.8 for this pack they say finish voltage shopuld be 4.2 per cell. But i wasn't able to get it that high.

But ran a second test with them floating at the 15.2 level. charge.

after coming off the charge they settled down to about 14.8 or so. They were stone cold throughout the charge and it took like two days to level off.

Ok, it ran again for about 11 hours or so, and it was still like at 12.5 volts. but wanted to see how long it takes now to get again to the 12 volt level. I leave it running, and about a hour later look at the UI View and last beacon was 20 minutes ago! YIKES! I go outside and check it. WOW when they say min voltage is 12 they mean it. it must fall like a rock after then. for it was all the way down to 3.8 volts!

I shut it down and started it on the yaesu charger again. it comes up the same as it did before except it will NOT go above 12 volts now. and once it got to the 12 volt point now the pack is warm to the touch. it never got warm the first time, but now refuses to go above12 volts and the pack is warm.

thoughts?

The deep discharge may well have killed one or more cells. Getting warmer
than normal and not taking a charge is a bad sign.

There is a steep falloff in the voltage as the cells hit the end of their
capacity. There's not much capacity left under 3.0V/cell. I try not to let
mine run under 3.3V/cell.

I have run Li-ion packs down to 2.0V/cell accidentally and was able to
continue using them. But I'm very cautious when recharging them after such
an event - I watch the temp and voltage very carefully when initially
charging.

LiPo packs are even more intolerant - I killed one pack after the first deep
discharge and the pack started swelling and heading when I tried to charge
it. Left it outside on the middle of a concrete pad for a couple of days
just in case it decided to burst or something worse.

6794. Shuttle reentry over CONUS tomorrow

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-18 20:02:41 UTC
From: Mark Conner
Topic: 6794 Message: 6794

http://spaceweather.com/

If all goes as planned, the shuttle will pass over the central US on its way to KSC early tomorrow morning. Ground track is approximately eastern MT/Sioux City IA/St Louis MO/Memphis TN/Tupelo MS/Columbus GA/KSC. Landing is at 1248 UTC and the shuttle will be over MT at about 1210 UTC.

Those near the ground track may hear the double sonic boom.

If it's delayed one orbit, the track would shift south somewhat. Bill WB8ELK in Huntsville will have a good seat for either opportunity.

Hi Tony....almost all of our early flights had an HF net either on 7.250 MHz or on 75m....but the 40m net seemed to work the best. The trick is to find someone that will dedicate to running the net.

The last one that went over our area a few years ago passed over Chattanooga, TN and along the AL/GA line about 80 miles away....I could see it zip from one horizon to the other in under 30 seconds going about MACH 15 and 230 k feet high....boy was it fast....it was right at sunset with the Sun behind my back so it stood out great....about 7.5 minutes later I heard a weak but quite recognizable double sonic boom.

Those of you to the NW of me will get quite a show as it blazes in just prior to sunrise.

Subject: See or hear Discovery during the landing approach Monday morning?

Hi all,

The space shuttle Discovery is scheduled to make a relatively rare "descending-node" landing early Monday morning. If the weather cooperates to allow a landing in Florida (rather than at the Dryden landing site in California), this may allow for a possibility of a sighting and/or hearing the sonic boom. Discovery will be doing between Mach 10 and Mach 12 when it makes its closest approach to the Huntsville area.

The first landing opportunity (orbit 222) for Florida has Discovery entering Alabama airspace near the NW corner and preceeding SE for a landing at KSC around 7:48am CDT. See the track here:
> http://spaceflightnow.com/shuttle/sts131/fdf/orbit222track.pdf

The second KSC opportunity (orbit 223) has the track over Alabama pass a little south of the previous one and should result in a landing about 90 minutes later or around 8:23am CDT. See the track here:
> http://spaceflightnow.com/shuttle/sts131/fdf/orbit223track.pdf

Neither path brings it really close to the Huntsville area, although I believe it may be just barely within line-of-sight, low to the SW. Also, I believe the Sun will have been up for at least two hours, so sighting Discovery probably isn't in the cards, but it might be possible to hear the sonic boom if you are outside and there's not much other noise. Don't have the exact time of closest approach, but it takes about one hour between the de-orbit burn and the landing. So, you could probably guessimate a good time to start looking and listening, and not have to spend a lot of time standing out in your yard looking up.

There's also the possibility of the landing being in California or at a later time (Tuesday morning), but I haven't seen any estimates yet about the likelihood of that happening.

Joe....with Li-ion and particularly so with the LiPo packs common in R/C aircraft....if you discharge below the minimum recommended voltage level, you have essentially turned the pack into a NON-rechargeable primary battery....they aren't kidding when they say to stop at that minimum voltage level....as Mark pointed out, you can sometimes bring them back, but often they are toast. I'd recommend a cutoff circuit when the cells get below that minimum level.

6803. Re: [GPSL] Li Batteries.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-18 23:42:39 UTC
From: Mike Manes
Topic: 6792 Message: 6803

That's dangerous, Joe. It's important to monitor the voltage of each cell in the series stack, both during charge and discharge, for max 4.20V and min 2.50 or 3.0V. Once a cell hits 4.2 during charge, the charge current must back off to keep the voltage at 4.2V, and that pretty much requires that each cell be charged independently. Letting a cell discharge too far risks developing a tendril short thru the separator matrix - and fire. And overcharging one past 4.2 also risks a fire due to outgassing.

These precautions are presented on the all-battery.com Li-ion web pages, and they require you to sign and mail in a signed affidavit committing you to abiding these rules plus a mess of others. At least, I had to.

Li-ion's are great for balloon payload, but one must treat 'em with respect.

6806. GPSL Update

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-19 01:08:19 UTC
From: Zack Clobes
Topic: 694 Message: 6806

Hello GPSL'ers...

Keith has the GPSL site updated with the schedule of events, including the various presentations on Friday. I think that I accommodated everyone's time request that they submitted originally, but if these times don't work, please contact me ASAP.

Like I said before, the hotels are filling up quickly, so please make your reservations NOW! :-)

Finally, I have some rough prices on helium. These are rough, include delivery charges, and the salesman expected that they very well could drop by summer. Once we get a little closer and have a firm price, I will get an online order form ready.

Helium Prices (including delivery charges):
K-Tank - $75 + tax
T-Tank - $88 + tax

I almost have the launch sites narrowed down, and hope to announce those this week. Any questions, comments, or concerns about GPSL 2010?

Zack Clobes, W0ZC

Hi Bill,

I remember seeing one like that as well. Its course was due south, and I both saw it in the eastern sky and heard the sonic booms from my backyard. I suspect it was the same landing you saw, and I seem to recall we discussed seeing it, maybe in emails. If I get around to it, I might try finding a reference to it in my archived emails, but I have no idea of when it happened.

As for trying to predict whether it'll be high enough and close enough to see, I reckon we could Google for more definitive landing profile information (altitude and location vs. time) and do some calculations about line-of-sight and know beforehand *OR* we could just go outside several minutes before the landing time and look out to the SW. Years ago when I was younger, I'd have opted for the first approach, but now the second appeals to me more.

Those who might want to try predicting the landing visibility from your own location might want to take a look at this page:

> http://www.nasa.gov/mission_pages/shuttle/shuttlemissions/sts131/news/131_landing_webfeature.html

I haven't tried it yet, but it looks like it might give the info needed.

The other variable in the equation (as if we needed another) is your local weather. You won't see the shuttle through a solid overcast, but you might hear it (although it wouldn't surprise me if cloudy skies might also soak up the sound to some degree). The forecast for here in north Alabama shows clouds starting to enter the area at just about the orbit 222 landing time, so we could be in good shape in that regard.

The NASA site I gave in a previous post does appear to work to give definitive sighting information (azimuth, elevation, range, solar altitude and separation) for shuttle landing paths for specific locations. To go directly to the Java-based calculator, go to:

>
http://spaceflight.nasa.gov/realdata/sightings/SSapplications/Post/JavaSSOP/JavaSSOP.html

For help with using the calculator, click on the 'intro', 'help' and 'FAQ' links above the map. IIRC I only entered my zipcode under the 'Map' tab and then under the 'Input' tab, selected the Satellite, such as 'KSC222(Entry).' My location and time zone correction data was already filled in from my zipcode entry under the 'Map' tab. Then I clicked 'Next Sighting' to get the table. I also clicked 'Print' to get it in printable form in my web browser (Firefox) from which I printed to PDF Creator.

It appears that both the orbit 222 and 223 landing opportunities will be within line-of-sight in the Madison & Huntsville Alabama area, with maximum elevations of 25.3 degrees and 14.7 degrees, respectively. Not great but possible if you have a relatively unobstructed view to the horizon to the SW. The calculator also gives landing data for other orbits and landing sites (KSC and EDW), but it appears that only the #222 and #223 landings work for the Madison/Huntsville area. Now, if only the weather will cooperate (both here and at KSC).

Don't know if the HARC and GPSL groups allow attachments, but I'll attach a PDF file with the #222 and #223 opportunities already calculated for the Madison/Huntsville area.

I've heard that it is possible to do a "shuttle bounce" off the ionized trail...you'd have to have two stations ideally located on either side of the trail with some power, CW or SSB and a nice antenna array with AZ/EL mount...for those who have been trying to hear Arecibo this past weekend on EME Moonbounce, you're all set for Shuttle Bounce....btw, we were at UAH campus at their ham ground station and could hear Arecibo on Moonbounce like they were locals....even on SSB....we were using a circularly polarized M2 42 element single yagi (22 elements in each plane)....the mast mounted AR2 preamp made the difference.

Subject: See or hear Discovery during the landing approach Monday morning?

Hi all,

The space shuttle Discovery is scheduled to make a relatively rare "descending-node" landing early Monday morning. If the weather cooperates to allow a landing in Florida (rather than at the Dryden landing site in California), this may allow for a possibility of a sighting and/or hearing the sonic boom. Discovery will be doing between Mach 10 and Mach 12 when it makes its closest approach to the Huntsville area.

The first landing opportunity (orbit 222) for Florida has Discovery entering Alabama airspace near the NW corner and preceeding SE for a landing at KSC around 7:48am CDT. See the track here:
> http://spaceflightnow.com/shuttle/sts131/fdf/orbit222track.pdf

The second KSC opportunity (orbit 223) has the track over Alabama pass a little south of the previous one and should result in a landing about 90 minutes later or around 8:23am CDT. See the track here:
> http://spaceflightnow.com/shuttle/sts131/fdf/orbit223track.pdf

Neither path brings it really close to the Huntsville area, although I believe it may be just barely within line-of-sight, low to the SW. Also, I believe the Sun will have been up for at least two hours, so sighting Discovery probably isn't in the cards, but it might be possible to hear the sonic boom if you are outside and there's not much other noise. Don't have the exact time of closest approach, but it takes about one hour between the de-orbit burn and the landing. So, you could probably guessimate a good time to start looking and listening, and not have to spend a lot of time standing out in your yard looking up.

There's also the possibility of the landing being in California or at a later time (Tuesday morning), but I haven't seen any estimates yet about the likelihood of that happening.

Topic: 6814 Message: 6814

I've been thinking about adding some twitter functionality to the launch announcement web site. But before I do it and spend the time on it I'd like some feedback.

1) Does your group have a twitter account?
2) Does anyone in your group use it?
3) Do you have a personal account, do you use it?

Twitter has a new CGI like interface called @anywhere, some of it's functionality might be useful on the announcement page or even on the primary ARHAB.org page. But again, is there any interest?

Any ideas how you would like to see twitter in use on these pages? Do you have any other ideas you would like to see implemented into these pages?

Thanks guys...

I use it myself and end most of my posts with #ARHAB. Perhaps every tweet
with #ARHAB could be displayed on the ARHAB page?

1. Yes
2. Sort of - I use it to post updates that show on our homepage (www.projecttraveler.org). I intend to utilize this during our 2010a launch to give live updates to those who aren't on the chase. I don't believe there are any/many others following my tweets.
3. Again, not really. I've only used it once to communicate with family when I was on a trip last year. Being tied to any old generic cell phone (with texting capabilities) it worked fairly well.

From: BASE
Topic: 6814 Message: 6817

BASE_DePauw has a twitter account, and we have about 20 followers. I also have a separate account where I follow other ballooning programs and activities (Superlaunch, EOSS, and as of now NearSys and ProjectTraveler). BASE_Depauw attempts to tweet about our flights. There is also a fan page on Facebook for BASE_DePauw. I have primitive links and connections between the Twitter, Facebook, and the program homepage.
Considering how simple my phone is, I'll have to do more pre-work to have the #ARHAB hash added to the tweets.

Joe,
The quick link appears to be empty, but I was able to run the satellite tracking applet that Bill mentioned from this page:
 http://spaceflight.nasa.gov/realdata/sightings/index.html
You will need to do some setup the first time to let the applet know where you are. You will need to select the satellite you want to track. For tomorrow, the first opportunity will be on KSC 237 (ENTRY) and the second on KSC 238 (ENTRY). I ran it with your Zip Code, and the first pass will be very good maximum elevation angle of 63 degrees. The second orbit won't be up high enough for you.

6825. MapPoint Add In for Predicting, Tracking, Reviewing Balloon Flights

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-20 00:44:46 UTC
From: jjdemeyer
Topic: 6825 Message: 6825

As you may recall, I discussed the development of a MapPoint Add-In, called Flight Track, for weather balloon flight prediction, tracking, and review at GPSL 2009. The Add-In is now available for download at

http://www.surfingsatellites.org/surfingsatellites.aspx?Page=FlightTrack.Download

The Add-In installs with sample flight data so you can immediately evaluate its primary functions. For more information, I invite you to review the Flight Track on line Help at

http://www.surfingsatellites.org/flighttrackhelp/fthelpcontent.htm.

Feedback and suggestions are welcome here

http://www.surfingsatellites.org/surfingsatellites.aspx?Page=FlightTrackFeedback&ContactSetUp=Feedback

Give it a try and let me know what you think!

Not totally sure if you're referring to me or not... I was using Map Point for my custom tracking software, but ultimately decided that MP couldn't keep up with the massive amounts of stations that get hit, especially when you're connected to the iGate.

I've since switched to a hybrid offline Google-map solution.

Not sure about the performance on this Add-In... just speaking from my experience.

6829. USB to 232 adapter showing up as mouse?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-20 02:52:52 UTC
From: Zack Clobes
Topic: 6829 Message: 6829

I'm having a problem, and I *think* I've narrowed it down as follows.

1. Fire up the GPS - 4800 baud NMEA
2. Plug GPS into USB-232 adapter
3. Plug USB adapter into PC (Win Vista or 7, 32 bit)
4. The cursor will randomly jump around the screen, occasionally clicking on things.

Tonight I noticed under Devices, it was actually showing one of my USB adapters as a mouse on Com6. I can still open the Com port in a terminal program correctly, it just messes with the otherwise tired mind.

Has anyone else run into this or know of a solution?

Yes, especially under WinXP. The GPS data can fool Windows into thinking it's a mouse. Do steps 3, 2, 1 in that order and you should eliminate step 4.

I have seen that on a few of my USB to Serial adapters on XP too. It was showing up as a Microsoft Serial Mouse. I disabled / maybe removed the Microsoft Serial Mouse and have not had problems since. Not sure if that was the cure or the right way to get the USB device identified correctly. It would only happen randomly with my USB adapters and I have not seen the problem in a while.

This is a known issue for 2000, XP, and Server 2003, though I've seen complaints on the topic on forms for Vista and Win7. Microsoft actually made a tool for the first three OS's mentioned... it can be found here: http://support.microsoft.com/kb/819036 ; might be worth a shot.

Keith and all....I have a Twitter account: WB8ELK but haven't used it much for flights as yet...maybe some of the next ones...I'd need someone who has the time to do tweet updates since I usually have my hands full with prepping for the flight. Also, Twitter is one of the web programs banned at my worksite, they'd come take my computer away if I attempted to follow a Twitter site.....so it isn't very useful to keep in touch or look at status updates while at my work....I can look at main webpage updates and that would be my preference for flight status updates.

Subject: [GPSL] Twitter Interest

I've been thinking about adding some twitter functionality to the launch announcement web site. But before I do it and spend the time on it I'd like some feedback.

1) Does your group have a twitter account?
2) Does anyone in your group use it?
3) Do you have a personal account, do you use it?

Twitter has a new CGI like interface called @anywhere, some of it's functionality might be useful on the announcement page or even on the primary ARHAB.org page. But again, is there any interest?

Any ideas how you would like to see twitter in use on these pages? Do you have any other ideas you would like to see implemented into these pages?

Thanks guys...

Hi Zack

Although the Microsoft utility to disable serial mouse detection mentioned in other posts will work, you have to apply it to every serial port. As you may have noticed, you each time you insert a USB-Serial device into a different port it can be detected as a different comm port, depending on what else is already installed. The best way I've found is to disable the serial mouse service entirely. Unfortunately it's hidden from the Services MMC snapin so you have to disable it via the registry.

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SerMouse
Change the value "Start" from 3 to 4

The only real drawback is that you can never use a serial mouse on your machine.

I'm having a problem, and I think I've narrowed it down as follows.

1. Fire up the GPS - 4800 baud NMEA
2. Plug GPS into USB-232 adapter
3. Plug USB adapter into PC (Win Vista or 7, 32 bit)
4. The cursor will randomly jump around the screen, occasionally clicking on things.

Tonight I noticed under Devices, it was actually showing one of my USB adapters as a mouse on Com6. I can still open the Com port in a terminal program correctly, it just messes with the otherwise tired mind.

Has anyone else run into this or know of a solution?

I'm close to that. I'm using a D-7 and Garmin GPS V. The screen on the Garmin is a bit small, but I find it easy to use as a backup tracker. As long as I know the expected recovery site, I can drive there and make updates based on my tracker.

I'm beginning to wonder how well a cell phone network USB card and laptop will work. We seem to get pretty good coverage out here.

Hey Bruce, Since you seem to know these kind of things maybe you can tell me how to tell what comm port is actually in use when I plug something into a USB port. I often plug in my Garmin GPS and am asked by the program what com port it is. If Windows doesn't know how the heck do I?

Thanks Bruce, I will try disabling that service. At this point in time, I hope my days of running serial mice are over...

Keith, the best thing I can say to determine your serial port is to look in Device Manager under Com Ports to see which com ports are actually being enumerated. Especially if you're running a USB to Serial adapter, its fairly easy to narrow down your options.

Also, you can right click on the serial adapter and go into properties. On the 2nd or 3rd tab (sorry I'm not in front of an adapter right now), you usually can set the com port that you want to use. The only issue with changing the port is that sometimes an old adapter that is no longer installed will still be holding that port, so it won't let you.

If you're running Win7 (and Vista I think), there's a Devices and Printers link right on the Start menu that will take you to a list of serial adapters.

Hi Keith

You could open Device Manager and watch what port appears when you plug it in, but that's a pretty clumsy way. I've often looked around for a quick and simple "show me my ports" utility but have never found anything I liked. BGIinfo will work but it works by redrawing your wallpaper so that's not always the best solution either.

Sorry, no bright ideas here today.

> Microsoft actually made a tool for the first three OS's mentioned...

David,

Thanks for mentioning this tool. I'm going to try using it
to restore com port operation on a PCI multi serial port card.

Nothing to do with false mouse recognition issues, it was more
to do with a situation I ran into where devices were being
assigned higher and higher port numbers due to "phantom" devices holding down lower
numbered ports that in reality were
unoccupied and available.

The higher number ports couldn't be accessed with certain
programs, so I followed a procedure found on the internet
that was supposed to remove the phantom port assignments to
make room for WIN2000 to add devices to the properly available
lower port numbers.

I ended up after all this with no serial ports being accessible
at all instead of three, 2 on the card and one on the MB.

Hank

Not totally sure if you're referring to me or not... I was using Map Point for my custom tracking software, but ultimately decided that MP couldn't keep up with the massive amounts of stations that get hit, especially when you're connected to the iGate.

I've since switched to a hybrid offline Google-map solution.

Not sure about the performance on this Add-In... just speaking from my experience.

Subject: [GPSL] MapPoint Add In for Predicting, Tracking, Reviewing Balloon Flights

As you may recall, I discussed the development of a MapPoint Add-In, called Flight Track, for weather balloon flight prediction, tracking, and review at GPSL 2009. The Add-In is now available for download at

http://www.surfingsatellites.org/surfingsatellites.aspx?Page=FlightTrack.Download

The Add-In installs with sample flight data so you can immediately evaluate its primary functions. For more information, I invite you to review the Flight Track on line Help at

http://www.surfingsatellites.org/flighttrackhelp/fthelpcontent.htm.

Feedback and suggestions are welcome here

http://www.surfingsatellites.org/surfingsatellites.aspx?Page=FlightTrackFeedback&ContactSetUp=Feedback

Give it a try and let me know what you think!

For weak packet sigs, it's important to have your receive audio level set
properly. Open the squelch and turn off software DCD in the TNC. On a
"dead" freq, adjust receive level (typically the receiver volume control)
until the TNC DCD lamp just flickers a little.

IF you have software DCD, you can leave your squelch open. Otherwise, set the
squelch just above where it silences the receiver.

Hi Don,

I didn't see any responses come back from GPSL, so I'll render my uninformed two bits: some of the EOSS trackers use the Kenwood D-7 HT with APRS/packet decoder and a port for NMEA from an external GPS. Fully configured, it will display not only the received APRS data, but also its bearing and range from your own position. Kinda handy, but pricey for an HT.

More guys use the Kenwood D-700 mobile rig, which also adds some more functionality.

I don't have either rig and rely on APRS-SA, Street Atlas and my GPS running on my laptop.

It's been a while, but Project: Traveler is ready to go again. We have a flight coming up on Saturday May 1 and I just ran the prediction using the new w3BalTrak online software (first time - I used to always do it via BalTrack).

Would someone mind validating that I chose the right options? I think all of the params can be found in the screenshot. I plugged in 13:00 for the time - I assumed that it was asking for zulu time? Does it matter? On the wind model, I chose May 1 @ 1800 UTC.

I flew my reliable RM-60 and the new Goldmine geiger counter on last weeks flight. I'm attaching a chart of the results.

The RM-60 has a mica window, so it records alphas, betas, and gammas. The Goldmine counter only detects betas and gammas.

Look at the difference. The Russian tube in the Goldmine kit is suppose to be sensitive.

Zack,
You did fine with everything. I usually use local 24 hour time also. The time choice in the data entry is not critical to the path prediction, although it does affect the T-minus time in the output display.
Your prediction would be for a flight on Saturday May 1 at 1 pm local time with the wind predictions from Hutchinson.
Sometimes I run predictions using different weather stations along the flight path. You might run with Salina also. Of course, as we get closer you can do the 3hr slices and watch the trend in the predicted path.

From: L. Paul Verhage
Topic: 6849 Message: 6849

The Jazz HD video camera has shut itself off in three near space missions.
I suspect its ON/OFF button is being pressed at balloon burst.

I've tested a suggestion or two and have discovered the following.

It doesn't shut off in a vacuum
It doesn't shut off if you drop it (at least four feet)
It doesn't shut off if you shake it

The camera has shut off just at the point of balloon burst while it was looking up. So next flight I'm going to point the camera at the hiorizon and see what happens.

I did cut back the holder for the camera on last weeks flight, but that flight ran an hour longer than normal, so it may have failed for another reason. The zoom button was pressed when the camera was loaded into its holder, so I'll modify its holder box for additional clearance.

There should be no structure behind any of the buttons of a camera. Else you take the risk of buttons being pushed while the camera is being loaded for flight.

Also, never depend on zip ties. It appears they get brittle in the intense cold of near space.

Burst can be pretty violent. I also had another thought about the burst itself, I imagine there is a substantial static charge at burst due to the shearing of the balloon / release of a foreign gas in such an environment, the static is likely huge up there on its own. I suspected that this might be the cause for some of us losing GPS lock. It might be worth wrapping the camera in aluminum foil to help shield the unit from the charge - ie Faraday Shield if you are sure the problem is not due to the buttons being physically pressed. I think this would be a fun experiment, sensing the level of static build up... Where do I hook up the ground wire? :)

On the last ARBONET flight, the burst was so violent that it broke the camera mount. This was a mount made of light aluminum sheet metal held in place by two long screws going through the 1" thick Styrofoam base with two fender washers on the opposite side. The burst itself broke the Styrofoam and on the way down you can see the payload housing, whereas on the way up you could not.

White zip ties are trash. Throw them away. :) Brittle at cold temps and brittle after only a little time in the sun. Use black UV rated zip ties, they do hold up in the cold and in UV. I used to install cell towers and microwave links, and you soon learn what zip ties are good and which are not. All of the clear/white zip ties I have tried failed in the cold or in the sun within weeks. I have black zips on these

towers that are still there after years in the Colorado sun and cold.

From: Mark Conner
Topic: 6849 Message: 6851

I have had cameras and radios shut off at ground impact (not burst, yet) where the battery compressed the spring to the point the other end broke contact briefly. I also try to make cutouts or otherwise keep any supporting material from making contact with buttons. With radios I normally turn on the "keypad lock" feature to mitigate it even more.

How about a timed auto shut off possibly? Have you ran the camera just
sitting on the workbench?

Also how about the battery drain? maybe just getting too low to
operate, but look fine power wise on landing? In other words, the
battery gets low enough to cause the camera to shut down, but now the
load is gone, so the battery now recovers to what seems to be a good
enough voltage?

Good thought, never thought of any static buildup and or discharge. i
wonder how far a balloon has to be to also protect from this if it is a
possibility? our balloons are at least 50 feet away on our radio only
flights,and on the video flights the balloon is as far away as possible
depending on launch conditions. always at least 100 feet and have even
come close to 300 feet.

We may try this on a future flight. I may have mentioned this on the list or at least to someone on the list, but how about a long shock absorber. Like a 20 foot length of latex surgical tubing below the balloon. to act as a shock absorber? When the balloon pops it takes all the forces of the nozzle going wherever it is going.

Thoughts?

On the first two videos I watched, the video ends after the same lenght of time as the balloon burst. There's no recording of the burst, so I suspect the camera is storing video onto the SD card in blocks. The camera gets shut off (at two different times) at the same time the balloon bursts.

The camera box is painted black, so it should absorb lots of solar radiation. at balloon burst the air has been warming for at least 30 minutes.

Topic: 6847 Message: 6854

Paul,
Geiger counters are essentially ionization event detectors. They don't care what the particle is, as long as it passes through the tube. The mica window for alpha detection is only valid for low energy alphas. High energy alphas can easily penetrate the metal enclosure around the gas-filled tube. In near space there are many energetic particles that enter the tube from all directions.
Based on the specifications the Goldmine tube is 97 mm long and 10 mm in diameter. The RM-60 tube is 38 mm long and 9 mm in diameter. The collection volume of the Goldmine is roughly three times the RM-60. This would lead us to expect three times the signal.
All of your data seems typical as to the count rate versus altitude. Your RM-60 data looks like what we have also seen in single tubes on our many flights. The Goldmine data is essentially 6 times the RM-60. We can find a factor of three from the volume. There is still a factor of two to be explained.

[Attachment(s) from L. Paul Verhage included below]

I flew my reliable RM-60 and the new Goldmine geiger counter on last weeks flight. I'm attaching a chart of the results.

The RM-60 has a mica window, so it records alphas, betas, and gammas. The Goldmine counter only detects betas and gammas.

Look at the difference. The Russian tube in the Goldmine kit is suppose to be sensitive.

Hi Paul,

It's possible that the camera has an accelerometer that keeps it from shooting if it's being jerked around, creating blurry image. And it's also possible that it's getting chilled out due to forced convective cooling that normally occurs during the high velocity post-burst descent rate. Painting the enclosure black may actually cause the internal temperature to become lower than if it were white due to radiative heat transfer, depending on its IR emissivity (some paints that look black in the visible spectrum are actually quite reflective in the IR. Carbon black pigment is a great black body with near-unity emissivity & absorbtivity). Radiative heat transfer probably dominates at 100K', at least during ascent, since air density is too low to provide much convection.

Is the flattening out of the Goldmine counts between 50K' and 100K' typical?
The RM-80 data appears to peak out around 70K'.
Might there be some corona discharge on the Goldmine device?

I've pumped the goldmine GC down and verified the corona discahrge was stopped. Let me try pumping it down again and see if it has failed after this flight.

The drop in cosmic rays should have occured around 62,000 feet, so the RM-60 looks pretty typical.

Mike and Paul,
The flattening is unusual. Perhaps the counter is reaching the limit for the tube or counting circuit.
As for the elevation for maximum counts, we have seen variations throughout our flights. It is not possible to conclusively say that the maximum occurs at a specific elevation. We don't have enough data to draw definitive conclusions. It may be as simple as the explanation for the seasonal variation in the altitude of the tropopause.

From: BASE
Topic: 6847 Message: 6860

Paul,
It is the Pfotzer maximum. Georg Pfotzer had a lengthy career as an atmospheric scientist in Germany. Early article in Nature in 1934 with Erich Regener -balloon carried a Geiger counter to 28 km! Finished his career as director of the Max Planck Institute in 1977.
Could you input a simple pulse generator to the BASIC Stamp. Based on the data from the Goldmine, if the Stamp handles a pulse rate of more than 100 Hz would indicate that it was not a counter problem.

I've pumped the goldmine GC down and verified the corona discahrge was stopped. Let me try pumping it down again and see if it has failed after this flight.

The drop in cosmic rays should have occured around 62,000 feet, so the RM-60 looks pretty typical.

From: Mike Manes
Topic: 6861 Message: 6861

Hi John,

It's tough to tell what balloon you have from just a diameter spec. Do you have a make & model? From LiftWin, I checked Kaysam and Totex 30 gm balloons, and found the two makes differ from 2.9 ft to 9 ft in burst diameter - and that makes a lot of difference in peak altitude!

Assuming it's a Kaysam with a 9 ft burst diameter, then 11 cuft of He will fill it to 2.8 ft diameter with 0.6 lb of neck lift. This would carry a 0.1 lb (45 gm) payload to about 30,000 ft MSL, where it gets pretty chilly outside - cold enough that your simple LC oscillator xmtr is very likely to drift, if not conk out entirely. And it may also travel several tens of miles downrange - past where it could be heard from the launch site even with a gain antenna and quiet receiver.

So I'd rate your chances at recovery as pretty low.

You might consider using one of the APRS beacons that many of the the other groups use, like a TinyTrak or MicroTrak.

I've watched the geiger counter operate on an o'scope (20 MHz). For every cosmic ray it detects, it produces 5 or 6 pulses due to the high voltage square wave it gets energiezed with. The BASIC Stamp shows this effect. On my YouTube channel, there's a video of this.

So the Stamp is counting the pulses.

I wonder if the tube is false triggering? Could something other than radiation cause it to trigger?

6863. Jazz Camera

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-23 12:59:59 UTC
From: L. Paul Verhage
Topic: 6863 Message: 6863

I shook and dropped the Jazz while it was recording. shaking didn't do anything. However, on two of several drops, I got the camera to shut off.

I need to take a closer look and see if I accidentally hit the ON/OFF button when I caught it.

I've dropped it before while it was turned on, but not recording, and didn't see it shut off.

Paul,
The multiple pulses per ionizing event could be a problem. I've forgotten how you compensated for those in your data collection/analysis (i.e, where do you account for the multiplicity?). Nevertheless, it would be interesting to see how your SBM-20 circuit functions in a higher radiation environment.
Combining the tripling of count rate for the SBM-20's volume compared to the RM-60 and the five or six fold multiplication for pulses per event, I would expect an even higher count rate at the Pfotzer maximum (9000 or more cpm).
If nothing else, perhaps I can find a source to bring with me to the GPSL in Hutchinson.

6865. Goldmine Geiger counter

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-23 16:54:20 UTC
From: L. Paul Verhage
Topic: 6865 Message: 6865
Attachments: 1 described; binary payloads are missing from this source WARC

I ran the gieger counter through the vacuum chamber. It's working fine (still). So the high counts and lack of drop off was not an artifact of corona discharge.

I've divided the counts by three to make comparing the RM-60 and Goldmine counter more valid. I'm attaching the spreadsheet.

6866. Geiger Counter Experiment

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-23 17:26:30 UTC
From: L. Paul Verhage
Topic: 6847 Message: 6866

I was noticing the variation in the counts for both detectors.

The RM-60 produces a smaller count and a narrower variation in counts (my ruler says the ratio is 3:9 at 60,000 feet).

The Goldmine detector has a higher count and a wider variation in the count rate (my ruler says 1:5.25 at 60,000 feet)

The variation in the RM-60 is 0.33 and the Goldmine is 0.19. That's a difference of about 50%.

I'll see if I can calculate what I would think is the standard deviation in the counts between the two detectors and if it changes during the mission.

The HV square wave period may be less than the plasma extinction time, and the pulses are actually measurements of the tube current. So if a 2nd, 3rd ... HV pulse comes along while the tube is still ionized, then they'll draw measurable current, and reenergize up the plasma to boot, thus exacerbating the problem. OK and perhaps preferable for audible monitoring, but it can produce the sort of high counts that maybe you're seeing.

From: Mike Manes
Topic: 6863 Message: 6868

The inertia of the button alone could have been enough to make a contact closure without actually touching it. This could happen if the camera hit the deck on side >opposite< from the on/off button. This kinda thing happened to the fast release arming bar during a launch with slack in the lift line before I statically balanced the arm and put in a stiffer spring. Expensive lesson ...

Paul,
Thanks for supplying the data file. To help me understand it, it appears that you take count data for 10 seconds and then multiply by 6 to get counts per minute. Is that a correct interpretation?
Although it is a small sample size, your count rates before launch for the Goldmine seem much higher than the 20 to 40 counts per minute that others have reported in the online literature.
Mike's comments about the HV power supply issue lead me to wonder if you are dealing with an instrumental effect.

Subject: Re: RM-60 and Goldmine
To: "L. Paul Verhage" <nearsys@...>

Dear Paul,

The Goldmine tube is Russian tube SBM-20. It has 1.05 times the volume of the RM-60's LND712, not 3 times the volume. The balloon group members that indicated the Goldmine tube has three times the volume where using the effective diameter of the LND712 window, which is 9.1mm, to calculate the volume but the effective diameter of the tube is 14.38mm.

SBM-20 Tube:
effective radius=5mm; effective height=83.5mm; effective volume=6558 cubic mm
Gamma sensitivity Co60 (cps/mr/hr) 22

RM-60's 712 Tube:
effective radius=7.19mm; effective height=38.1mm; effective volume=6188 cubic mm
Gamma sensitivity Co60 (cps/mr/hr) 18

I just talked with LND about the size of the 712. The above figures are correct. On LND spec. page they say in two places the effective diameter is 9.1mm but in both cases they are meaning window diameter. The effective tube diameter is as per our website 14.38mm i.e. 15.1mm outside diameter - (wall thickness 0.381 mm x 2)=14.38mm effective diameter. LND is going to add this to their spec. page to make it clear the 9.1mm is the window diameter and 14.28mm is the wall effective diameter.

http://www.aw-el.com/specs.htm
http://www.aw-el.com/tubegrap.htm

http://www.aw-el.com/russian/2398_1.gif
http://www.aw-el.com/russian/SBM-20.JPG

If all is well, the SBM-20 should generate count rates just about the same as the RM-60 (except RM-60 is more sensitive to lower energy betas and gammas as well as alphas). I have heard from several sources the russian tubes are surplus over 30 years old, many with odd problems like quench and

that perhaps the circuit used is to prevent lack of quench multi pulse or runaway pulse.

In your balloon data, notice if you multiple the RM-60 10 sec. counts by ~ 18, the curve looks the same as the russian tube 10 sec. counts i.e. before the russian tube tops out, the variation in the graph line is about the same as the variation in the RM-60 data curve times 18. This indicates there's something wrong with the russian data.

Mr. Boardman, one thing the balloon group has mentioned is that the Goldmine tube has three times the volume of the RM-60 tube.

Would it make sense it should detect three times the cosmic rays?

Paul

On Thu, Apr 22, 2010 at 12:57 PM, Bryan J. Boardman / Aware Electronics Corp. <boardmanb@...> wrote:

Hi Paul,

I saw your graph re RM-60 and Goldmine on the latest balloon 10A. The Goldmine data looks strange. I have learned that the tubes from Goldmine are at least over 30 years old. They look like they have old bakelite insulators on the ends. (http://en.wikipedia.org/wiki/Bakelite) I guess it is possible Goldmine gets semi-defective old tubes for even less money, that are good enough to blink their LEDs or qualitative work but not quantitative work.

I do know that old tubes can lose their quench abilities due to things like quench gas absorbing on to things like a solder blob, plastic etc., which would cause several or more pulses per detection, in a random like manner or even run-away oscillation.

Notice how at 0 altitude the Goldmine has quite a spread similar to the spread at 60,000 feet. This would indicate there is something wrong with the data.

If you would like me to look at the data and comment back to you about it, feel free to send the data to me as well as where on the schematic you

picked off the signal.

Paul,
Obviously, if you use the numbers that Mr. Boardman has you will get his results. I simply used the window dimension from the Aware website (which Mr. Boardman noted) and the Goldmine dimensions for the SBM-20 (which are evidently external numbers). The count rate is still volume dependent.
The age of the tube can contribute to the problem. Although halogen (Br2) tubes survive much better than organic vapor tubes.
I still wonder about the power supply. For fun, it would be nice to run the SBM-20 on the RM-60 power supply and the LND712 on the Goldmine supply.

6872. Project: Traveler flight announcement

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-25 02:39:06 UTC
From: Zack Clobes
Topic: 6872 Message: 6872

Traveler will be launching next Saturday May 1st from the Hutchinson airport (KHUT), in conjunction with an airport open house.

We will be flying our standard custom APRS controller board (AJ0NR-11), as well as a brand new Arduino/Inventek combination board (W0ZC-11). We will also be flying a Canon A570IS camera with the CHDK firmware. The balloon is a 1000g, total payload is just under 4lbs, and I expect a standard 1100/1200 ascent/descent.

The open house will have pancakes available starting around 7:00am, and launch preparations will start around 7:30. I anticipate an 8:30am release, although may vary significantly depending on surface conditions and the number of questions we receive from the attendees.

Initial flight predictions are showing a touchdown somewhere in the Herrington to Manhattan, KS area.

Open House Information: http://www.wellsac.com/open_house.php

Been thinking here,

OK, we know that at sunset A Balloon looses about 10% of the daytime value of lift. (rough average number) Because it is not getting the solar energy.

So then let me confirm that a balloon inflated in the dark at night of course won't loose any true? it's already dark, but at sunrise it should gain about 10% right?

Now something strange to think about.

especially for our group that i actually have never thought about before.

When inflated inside a building, is that the same as night time filling? it's not getting any solar benefit.

And once the balloon is taken outside does it then get that added 10% gain in lift because it is now getting the solar energy gain?

How about the guys that fill FAST!!! the gas has to be super cold now. by the time it warms up are they getting a lot more lift than they actually thought they had because of the gas warming up?
Just thinking here.

I lost it, but someone discovered a very small and lightweight solenoid valve that runs on like 12 VDC or similar.

where was this valve available from?

Hi Joe,

On one flight, we filled before dawn, and had to wait a spell for the student payloads to get prepped. In the meantime, the sun rose and illuminated the balloon. Voila! The tare weight lifted off the deck smartly! Sure glad we had it tethered separately.

I think this has to do with possibly greater IR absorbtivity of He vs air, which also explains why ZP floaters sink at night.

James May from the awesome show "Top Gear" on BBCA is going to fly in the U2, and from the previews he gets right up there for sure. While not ballooning,, it's still in the levels we play in, and these guys from "Top Gear" are always hilarious.

It starts in less than a half hour 7 PM CDT on BBCA BBC America

Hi John,

Well, I'm guessing that those balloons aren't meteorlogic quality if they
didn't come with at least a mfr insert - so they may just be party balloons.
Latex met balloons have a milky appearance, unlike the nearly transparent
skin that your video shows.

From the burst diameter that you gave for the 17" bag, the closest Totex spec
I could find on LiftWin was a KCI 20, 20 gram latex, which may be where the
"20 gram balloon" title on your video came from. If that's close, then
a fill to yield 35 gm (0.077 lb) of neck lift with 20 gm (0.044 lb) neck
load, then LiftWin predicts an ascent rate of 470 fpm and burst altitude
of 34,000 ft MSL.

LiftWin 041 is downloadable from http://www.eoss.org/balsoft.htm
where you'll find guidance on running it under Windoze 98 thru 7.
It's an invaluable resource that's used by most ARHAB groups.

You may also be interested in downloading Balloon Track, a trajectory
prediction app that uses the latest measured or forecast winds aloft
models. A good forecast is invaluable to a successful recovery effort.

And I'd also recommend that you join up on the GPSL email reflector, where
a broader range of groups hang out; I've cc'ed this reply there.

6888. Any discussion regarding the use of a rubber ducky antenna on a payload?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-29 00:52:32 UTC
From: Zack Clobes
Topic: 6888 Message: 6888

I'm doing final flight testing before our Saturday launch, and ran into a situation. I believe that I have it resolved, but wondered if anyone else had done any testing.

Situation:

- Brand new design, relatively untested Controller/TNC/GPS board design.
- Radio Shack ~.25W HT with SMA-based rubber-ducky (sorry, the model number got Velcro'ed over).
- Soft foam padding packed into a cloth lunch bag/cooler (11" x 6" x 7"). There are pockets cut into the soft foam to hold the transmitter, controller, camera, etc.

The controller board has been under development for a couple of months now. I recently got the PCB back, and put the prototype board together. Signals cabled directly between the board and a Receiving KPC-3 TNC were perfect 100% copy. I attached the Radio Shack HT with a ~6" cable, and on the bench I was still receiving a ~90% copy over the air.

About a week ago, I put together the lunch box with foam, and wound up putting the transmitter and board back-to-back in a piece of foam, separated by a couple of inches. The setup actually worked pretty good considering the proximity (no lock-ups, no RFI). Again, the system worked good sitting here on the bench, maybe a little worse, but definitely > 75% copy.

I picked the bag up, and walked out into the front of the house, and hung the capsule from a tree about 5' in the air. The transmitter is now about 40' away from my base antenna, virtually line of sight. Back downstairs, my TNC receive rate has dropped down into the 20% range. If I turn PASSALL ON, I can probably recover about 60%, but many of the packets are visibly and obviously garbled.

Placing the Tx and Controller back-to-back wasn't intentional, but that's how it laid out with the camera getting in the way. Thinking that I had an RFI problem, I moved the camera to the far end of the capsule, literally stretching the interface cable tight (the same cable that I have used during all of my testing). I also slid the radio up, placing the base of the antenna above the entire Controller board. Again, in the basement next to the Rx, I get 75% copy, and outside I drop into the 20%'s.

Desperation sets in, and I rip an old 1/4 wave dipole antenna from a prior flight box, and glue it to the side of the lunch bag. I plug the SMA connector into the HT, and bingo, I'm back to >= 80% receive rates, pretty much regardless of distance. Because of houses/trees/street-layout, I don't have good line-of-sight options to test from my house, but I was able to

drive about .5 miles away and around the corner and receive >> 50% without line-of-sight conditions.

So, I'm wondering if anyone has any theories. I briefly looked at the received audio on the 'scope, and I did not see any RF or extraneous noise on the signal. I'm starting to wonder if it wasn't somehow an SWR issue. Normally the human holding the transmitter completes the bottom half of the antenna, and obviously this isn't happening inside of a lunch pail...

Offhand, I'd say your rubber duck or cable was bad. I've had situations where the copy was great on the bench or over a few feet, but degraded rapidly with distance. That would seem to indicate RF not really getting out, especially when you replaced it with a dipole and got good copy at a distance.

I use a 3-4" aluminum square in the top of the lunch cooler with a SMA bulkhead connector in the center. It's not an ideal ground plane for 2m, but seems to be enough and is better than no metal at all.

Bad news

Apparently the launch went bad and the payload was dragged or something. It destroyed a car and broke in thousands pieces.

More to come

I wouldn't dismiss the bad antenna theory, and I really don't have any way to "accurately" test a tiny rubber duck. I can say though that the S meter was showing full strength even with lousy copy.

I didn't replace or repair the cable though, and there were only two wires (ground and mic/PTT). For what it's worth, I'm not feeding power to the radio from the Controller. The radio is using its internal AA batteries.

From: DON FRASER
Topic: 6888 Message: 6893

Had a similar problem with a USAFA (Air Force Academy) payload maybe 15 years ago & like you it worked great in the lab but not at any distance.

We swapped the location of the tx (to outside) and rx (to inside) and it started to work like it should. Later analysis suggested that the problem was phase jitter if you will.

On Wed, Apr 28, 2010 at 19:52, Zack Clobes <zclobes@...> wrote:

I'm doing final flight testing before our Saturday launch, and ran into a situation. I believe that I have it resolved, but wondered if anyone else had done any testing.

Situation:
Brand new design, relatively untested Controller/TNC/GPS board design.

Radio Shack ~.25W HT with SMA-based rubber-ducky (sorry, the model number got Velcro'ed over).Soft foam padding packed into a cloth lunch bag/cooler (11" x 6" x 7"). There are pockets cut into the soft foam to hold the transmitter, controller, camera, etc.

The controller board has been under development for a couple of months now. I recently got the PCB back, and put the prototype board together. Signals cabled directly between the board and a Receiving KPC-3 TNC were perfect 100% copy. I attached the Radio Shack HT with a ~6" cable, and on the bench I was still receiving a ~90% copy over the air.

About a week ago, I put together the lunch box with foam, and wound up putting the transmitter and board back-to-back in a piece of foam, separated by a couple of inches. The setup actually worked pretty good considering the proximity (no lock-ups, no RFI). Again, the system worked good sitting here on the bench, maybe a little worse, but definitely > 75% copy.

I picked the bag up, and walked out into the front of the house, and hung the capsule from a tree about 5' in the air. The transmitter is now about 40' away from my base antenna, virtually line of sight. Back downstairs, my TNC receive rate has dropped down into the 20% range. If I turn PASSALL ON, I can probably recover about 60%, but many of the packets are visibly and obviously garbled.

Placing the Tx and Controller back-to-back wasn't intentional, but that's how it laid out with the camera getting in the way. Thinking that I had an RFI problem, I moved the camera to the far end of the capsule, literally stretching the interface cable tight (the same cable that I have used during all of my testing). I also slid the radio up, placing the base of the antenna above the entire Controller board. Again, in the basement next to the Rx, I get 75% copy, and outside I drop into the 20%'s.

Desperation sets in, and I rip an old 1/4 wave dipole antenna from a prior flight box, and glue it to the side of the lunch bag. I plug the SMA connector into the HT, and bingo, I'm back to >= 80% receive rates, pretty much regardless of distance. Because of houses/trees/street-layout, I don't have good line-of-sight options to test from my house, but I was able to drive about .5 miles away and around the corner and receive >> 50% without line-of-sight conditions.

So, I'm wondering if anyone has any theories. I briefly looked at the received audio on the 'scope, and I did not see any RF or extraneous noise on the signal. I'm starting to wonder if it wasn't somehow an SWR issue. Normally the human holding the transmitter completes the bottom half of the antenna, and obviously this isn't happening inside of a lunch pail...

Hi Zack,

We used to run into mysterious irreproducible stuff like that until we switched over to a wire J-pole separated from the payload enclosure with about 3 ft of RG-142. It seems that xmit RF from the antenna, or common mode RF conducted up the feedline, was getting into the sensitive bits inside the payload (analog stuff and a 3V uP most likely). This was discovered by observing that the problem disappeared when the antenna was replaced with well-shielded dummy load.

Ugh. Shades of EOSS-5(?) - our first experience with a plastic balloon
and high winds :=(. Fortunately, no cars were harmed, and only a few
pieces broke free when the payload was dragged across a parking lot
before striking a snow bank.

I was wondering why they were doing this flight so late in the morning. Obvious a decent amount of wind there.

Shame we lost the video prior to launch.

HLN/CNN showed the destructive launch of this balloon this morning.

I was wondering why they were doing this flight so late in the morning. Obvious a decent amount of wind there.

Shame we lost the video prior to launch.

Bad news

Apparently the launch went bad and the payload was dragged or something. It destroyed a car and broke in thousands pieces.

More to come

In the video it looks like they got more wind than they were hoping for, and were turning the launch crane, to drag it more up wind, and when it got totally sideways to the crane it became un attached. In an audio report from a key person they say that there was a mechanical malfunction on the launch system on the end of the launch crane released early.

I wonder if the launch release rig failed. It was obvious from the camera angle the launch was not going to have a good outcome, and it appeared the crane was swinging up-wind when the payload broke away - it should be facing down wind.

And how do you explain to your car insurance agency that your off-road capable Land Rover was just hit and rolled by a helium balloon... :)

I can imagine the response: "Yah, right... I now have heard it all... Now what is the real story?"

One of our launches was under the same circumstances, where the balloon was downwind and the payload released. It crashed into the ground as the payload out ran the balloon speed, causing the payload to stop working. Not as big time as this Nasa launch, but the same learning experience! We now pull the balloon way up wind and release with a long release line, assuring the payloads are in headed vertical and not horizontally at release.

Out of CSBF, Tiny Tim, the crane holding the payload, runs downwind before releasing the payload. That way the payload is directly beneath the balloon when the load line is tight.

Here's a some text explaining a little more of the science.

http://news.yahoo.com/s/space/20100429/sc_space/hugenasascienceballooncrashesinaustraliano
utback

Also contains a few seconds of video not presently at the
ABC website.

If anybody can find footage showing a minute or two *before*
the balloon envelope was released from the giant reel, that
would be really most valuable to more fully understand what
went wrong.

To hear the preliminary, all too brief and undetailed
explanation of the failure from UC Berkeley doctoral student
Eric Bellm, click on the audio file button at the basic
ABC webpage:

http://news.yahoo.com/s/space/20100429/sc_space/hugenasascienceballooncrashesinaustraliano
utback

(Cut to the chase by advancing the playback cursor to about
2:03 remaining.)

To see how this can go right during dead calm conditions, and to
see the giant reel release I mentioned above, see this video of the earlier picture-perfect
launch of April 16:

http://www.abc.net.au/news/stories/2010/04/16/2874597.htm

Hey all,
This sort of crash isn't that rare in the scientic launching world in my experience - the launch teams are usually quite good at not letting the details get out - guess thats one of the issues with publicising launches.

I experienced a similar situation occurred while out in Africa launching with CNES - a hole in the balloon envelope led to helium escape before launch so that on release there wasn't enough lift - the balloon was able to lift most of the payloads on the payload train but couldn't lift the largest one at the bottom. This resulted in the train being dragged for 3 miles getting very close to the runway of the nearby international airport. Amazingly the payload at the bottom actually survived pretty much intact only 1 of the 2 glass gas syringes was broken. When these balloons do work out its very impressive to watch.
Some pictures of that campaign:
http://www.flickr.com/photos/jcoxon77/sets/72157614028027899/

Hope the payloads are at least slightly recoverable!

I can't believe this stone-age method is still being employed.

Looks like it creates unnecessary exposure to serious injury to
the guy standing so close to that reel contraption so he
ca strike the retaining latch, or to anyone else should it
release prematurely.

Couldn't there be a mechanical safety that would be released by
hand to "arm" the reel mechanism latch, and THEN a remote control
by cable from some safe distance (say 100 feet) for the actual release of the reel to free
the envelope?

The way they're doing it looks crazy dangerous to me. Look at
the way that reel slaps and the recoil of the truck!

If I were in charge that method would not be allowed, period.

Hank

My thoughts of the motion of that hold down unit is to it is made to
move that way on purpose. So that it gets out of the way of the balloon
envelope NOW so that there is no sliding of the film across anything at
all. for in it's fragility i'm thinking any sliding is a hole just
waiting to happen.

Sure it's made that way for the reason you state. I would
not change anything about that part of the basic mechanism,
just the method of release so that a person does not have to
stand next to it to strike it to let it rip (pun recognized).

Well, the launch crane, aka "Tiny Tim" is supposed to keep the payload directly under the balloon during launch. That clearly didn't happen, so maybe the failure was that Tiny Tim's engine conked out - it didn't appear to making any progress. The payload gets released from the crane when it's weight gets taken up by the lift line - which kinda did happen, except sideways.

We had a similar mishap on our first NOAA GAINS launch out of Meadow Lake airport near Falcon CO - with yet another plastic balloon. Wind was calm during fill, but launch was delayed due to payload telemetry issues, during which the wind cropped up.

We instruct our payload handlers to do what Tiny Tim was supposed to do:
move to stay directly under the balloon during launch. Fortunately,
our payloads are light enough to use human "Tiny Tim's" :=).

From: BASE
Topic: 6913 Message: 6913

Dear friends,

Despite the troubles encountered in Australia (which three colleagues stopped by to tell me about during our pre-flight preparation), BASE 42 was completed today, with only the typical minor problems.

Launch in 21+ miles per hour winds went smoothly. The tethered release was very helpful (Thanks, Joe).

Flying 10.5 pounds on a 1200 gram balloon with 1300 ft/min ascent resulted in burst just above 86 kft.

Recovery was easy since no corn or beans have yet to sprout upward to hide the payloads.

Had the help of Ron, N9QGS, whose rebuilt tracker went along for a test ride. Also had Jay, KC9QOW and his colleague from Terre Haute at the launch. They also tracked the flight.

Thanks to all for your support,
Howard

From the stills showing the fill, the winds were dead calm. But the video starting post-release and showing the gory details of the payload drag indicates that there was at least 10 kt - maybe more - wind upon release.

It gets real dicey to be the guy stuck with the go/no-go decision, once a huge sum has been expended already just filling the balloon, since a no-go means firing the balloon destruct and wasting it and all that gas for nothing. Not to mention the payroll for the launch crew and the experiment teams.

Been there, done that, got a few lousy T-shirts, with the biggest difference being the magnitude of the money and effort, not to mention face, lost. This is why EOSS always carefully evaluates the forecast launch conditions up to T-12 hours, and calls a no-go before anyone deploys to the launch or recovery sites. Any chance that surface wind could hit 10 kt is a no-go and scrub to the weather date - hands down. That sure beats postponing that call until everyone's already in the field - and that could include 10 vans with 50 students. Even so, that call creates heartburn when the students have booked non-refundable flights out the next morning :=(.

NASA applies the same policy, but in this case, there may have been some other, as-yet undisclosed, drivers pushing the launch at any risk. Could be a day's delay would have fallen outside of the experiment's observation window, e.g.

There's a few hundred feet of taut lift line between the bottom of the envelope and the Tiny Tim, so the entire envelope is aloft before coming anywhere close to it. And these launches typically require calm to light surface winds so that the uninflated envelope simply lifts directly upward without being dragged horizontally. It's pretty certain that those launch winds at Alice Springs came as huge surprise.

6918. Cellphones in balloons legal?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-30 04:14:03 UTC
From: wb8elk@aol.com
Topic: 6918 Message: 6918

Hi Scott....Ron was using the EVDO card in his car to send the reports via a UI-View I-Gate in his car, not in the balloon.

Using the cellular phone network from a balloon is something that a few folks including the MIT students are promoting to the general public as a primary balloon position reporting method (even though it would appear to be prohibited even in balloons by regulation CFR# 22.935 - link shown below - Mike Manes of EOSS previously posted a similar link on this topic)....The method being promoted to the general public for balloons involves using cheap Boost Mobile cell phones with built-in GPS. They use websites such as Instamapper.com or accutracker.com to see their reports....usually due to the nature of cell networks, once the balloon is high enough to hit multiple cell sites, no one wins and they get nothing back. I have a terrible time of it trying to use my cell phone even at my mountaintop house and I'm only 500 feet above average terrain....The MIT students got very lucky on their first flight and had a hit just before they landed and very spotty coverage during most of the flight on their first mission, but had nearly zero results on their next few missions. One of them did get his ham license and now uses amateur radio tracking with good results.....however, they still promote cell phones on their online Balloon Guide. Also, the Instamapper website (or perhaps the output of the Boost Mobile cell GPS) truncates the altitude above 22,000 feet so even though they might get some coverage higher than that, it just keeps reporting 22k feet. The only good use for cell phones on balloons would be as a backup recovery method as long it's in range of a cell tower once on the ground. So as a "Phone-Home" use after landing a cell phone system could be quite useful as a backup for APRS. However, it's much better to use a FindMeSpot unit for that as I've had great results using a Spot as backup recovery info once landed. I've already received a number of emails from folks who lost their cell phone balloon payloads and are asking about better ways to track them, so I try to steer them towards the amateur radio route.

The most successful use of cell phone reporting from a balloon was done by the innovative Ivory Copter folks (using a bunch of mylar party balloons) who pointed a directional antenna straight down from their payload, but even then they had spotty coverage. They were even sending down live still photos during the flight from the cell phone camera. Since they are on one of these lists, perhaps they can offer some insight into the legality of using cellphones from balloons....it's possible that there is an exception to the rule for unmanned research balloons but I haven't found that info as yet.

I found this posting about cell phone usage in balloons and airplanes which seems to be quite clear about not using cell phones while airborne even in balloons:

>Cellular telephones installed in or carried aboard airplanes, balloons or any other type of aircraft must not be operated while such >aircraft are airborne (not touching the ground). When any aircraft leaves the ground, all cellular telephones on board that aircraft must >be turned off.

CFR regulation # 22.935
http://edocket.access.gpo.gov/cfr_2006/octqtr/pdf/47cfr22.935.pdf

So in addition to the fact that government regulations appears to prohibit it, the very nature of cell tower sites means that it doesn't work well during flight.

Much better for license-free balloon flights to use Maxstream 900 MHz units (such as the 9Xtend) with the FindMeSpot as a backup.

However, the price will be substantially more than the $150 cost mentioned by the MIT balloon guide (our normal ARHAB flights will usually cost more than that just for the balloon and helium/hydrogen). That is only achievable by using very small eBay surplus balloons, donated helium or hydrogen and then you'll still be nearly $200 for the Maxstream unit by itself....a safe estimate for a license-free payload using a Maxstream 9Xtend, GPS receiver and Spot payload cost would be about $400....not to mention the ground station costs of $200 for the ground unit, $50 to $100 for the antenna and the $149 a year subscription for the Spot unit.

So getting your amateur radio license would appear to be a fiscally responsible thing to do if you're planning to get into high altitude ballooning as you then can utilize the extensive APRS network and entice all those balloon-chaser hams who will happily climb remote mountains, hike into "Deliverance Country", scale trees, risk stampeding buffalos and tromp through alligator-infested swamps without hesistation in their quest to find your APRS balloon payloads.

ronald74 wrote:

Hi Folks,

I won't steal Howards thunder, but we flew two GPS trackers N9QGS-11 and
W9YJ-11, both worked well, and with the use of a EVDO card in my vehicle
we were able to bring the data all the way down to the ground.

Prediction software were very accurate today. it was just a perfect
balloon recovery, about 20 to 30 feet off the side of the road in farm
field that has not started sprouting anything, so it was a 10-15 second
walk from the car to snatch it.

>From my aspect, I was in general satisfied with the first use of an
EVDO to bring the balloon data all the way to the ground. But I had some
other complication going on with the GPS side inside UI-View mainly I
believe with a program GPSGate locking up and not recovering causing me
to loose GPS position within UI View. I may try by-passing this and
using a serial GPS with a Serial to USB adapter.

I was not able to keep up with anything more than UI View, but someday maybe streaming a recovery would be neat to try.

No, we don't. But that's why we launch at sunrise, when the winds
pass thru a null due to heating on the tops of the Rockies.

The crane used in Australia is not "Tiny tim". Besides... tiny tim is not working anymore... the last launches from Palestine were performed transporting from Fort Sumner the "Big Bill" launch vehicle.

Interesting, I had no references of the GAINS launch in CO... iy you want please let me know more in a private message.

best regards

I just ran a prediction for tomorrow morning at the Near Space ventures site.

wow the winds are bad for tomorrow. i filled in the data as seen here.

But the summary at the right side of the google map track page in one spot says in the launch box summary it has max altitude as specified in the data entry form the 123,000 feet.

But in the burst box it says that burst is at just barely over 105K, why is that?

Kaymon is out of there 1200 gram balloons and don't know when they'll be back in stock. Has anyone run into a problem liek this with Kaymont? They've been good for me in the past, but I haven't had to order a balloon in over a year.

Also, what is the name of the other supplier people have used, was it Scientific Supply? As I recall, they were rather pricey.

Thanks

Joe,
One problem is the lack of good wind data for altitudes above 105,000 feet. Actually, the Near Space Ventures program uses the GFS models that stop at 87,000 feet. Any burst altitude above that assumes the same wind velocity at all higher altitudes. Perhaps Troy can share why the extrapolation only goes up to 105 kft.
Balloon Track (from Rick vonGlahn) allows you to use actually sounding data or a blend of model winds at low altitudes and sounding data at higher altitudes.. The Green Bay balloon had a good climb this morning to over 108,000 feet.

Joe...since the GFS model stops at 87k feet as Howard mentions, your best option for such a high altitude flight is to download the actual PC version of Balloon Track from the EOSS website and blend in the nearest radiosonde site to your data.

Another possibility is to hand-jam the high-level sounding wind data
(converting from knots to meters/sec if necessary) after doing the
cut-and-paste operation in the on-line version. I've done that a few times
and it seems to work fine.

Mark...I've done that too and it works....actually one of the advantages to their new cut and paste wind data entry method that was not possible with the former automated wind data mode.

Another possibility is to hand-jam the high-level sounding wind data (converting from knots to meters/sec if necessary) after doing the cut-and-paste operation in the on-line version. I've done that a few times and it seems to work fine.

Joe,

One problem is the lack of good wind data for altitudes above 105,000 feet. Actually, the Near Space Ventures program uses the GFS models that stop at 87,000 feet. Any burst altitude above that assumes the same wind velocity at all higher altitudes. Perhaps Troy can share why the extrapolation only goes up to 105 kft.

Balloon Track (from Rick vonGlahn) allows you to use actually sounding data or a blend of model winds at low altitudes and sounding data at higher altitudes.. The Green Bay balloon had a good climb this morning to over 108,000 feet.

I just ran a prediction for tomorrow morning at the Near Space ventures site.

wow the winds are bad for tomorrow. i filled in the data as seen here.

But the summary at the right side of the google map track page in one spot says in the launch box summary it has max altitude as specified in the data entry form the 123,000 feet.

But in the burst box it says that burst is at just barely over 105K, why is that?

Hi Luis,

Here's a recap of EOSS-59, the GAINS I flight with a wind-damaged plastic balloon:

http://www.eoss.org/ansrecap/ar_060/recap59.htm

There are lots of links for more details than you'd ever care for, but no videos were shot at launch.

This photo sequence is best we have of the launch drag:

http://www.eoss.org/ansrecap/ar_060/recap59h.htm

If that drag had lasted a bit longer, we'd have smacked a Cessna King Air rather than an SUV :=(.

Thanks for the update on Tiny Tim, whom I met at Ft Sumner back in 1994. He will be missed. However, I hope that term effectively serves as a generic title for machines that serve that function.

BTW, there's an excellent video showing exactly how Tiny Tim is supposed to operate. It was a documentary of a huge launch of a Microwave Background Survey instrument from Sweden that cruised W at a tall float altitude, landing a few days later in Canada. Seem to have lost track of the URL.

6933. Re: [Balloon_Sked] Cellphones in balloons legal?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-04-30 21:06:51 UTC
From: wb8elk@aol.com
Topic: 6933 Message: 6933

Hi Chris....so according to that, using the PCS and AWS bands would be legal for airborne operations since those frequencies aren't spelled out in CFR 22.935? I have read that the new 700 MHz band is where some companies plan to operate balloon wireless internet and cell systems.. Also, your take on the interpretation of what constitutes a "Cellular Telephone" could mean that the 869 to 940 MHz Cellular Band is usable for airborne data applications but not voice telephony. But I also agree that a GlobalStar modem such as is inside the FindMeSpot unit would be a better method than using a cellular method. Thanks for clarifying that. - Bill WB8ELK

Wiki excerpt:

The Cellular band (869-894 MHz) is divided into 2 frequency blocks (A and B). There are 306 Metropolitan Service Areas and 428 rural service areas. Each trading area consists of one or more counties.

The PCS band (1850-1990 MHz) is divided into six frequency blocks (A through F). Each block is between 10 MHz and 30 MHz bandwidth. License (A or B) is granted for a Major Trading Areas (MTAs). License (C to F) is granted for a Basic Trading Areas (BTAs). There are 51 MTAs and 493 BTAs in the United States.

The AWS bands, auctioned in the summer of 2006, were for 1710-1755 MHz, and 2110-2155 MHz. The spectrum was divided into blocks: A blocks were for Cellular Market Areas, based on existing cellular (1G) licenses, and were 2x10 MHz. B and C blocks (2x10 MHz and 2x5 MHz respectively) were for Basic Economic Areas, larger than CMAs, usually comprising of large portions of single states. D, E, and F blocks covered huge areas of the country, typically several states at a time, and covered 2x5 MHz for D and E blocks, 2x10 MHz for F.[1]

The 700 MHz band was auctioned in early 2008, with Verizon Wireless and AT&T Mobility winning the majority of available spectrum. Qualcomm and Echostar were winners of a significant amount of broadcast-oriented spectrum. The winners have not yet announced what technology they intend to deploy on this spectrum, but it is expected to host a range of 3G, 4G, and broadcast technologies such as MediaFlo and DVB-H.

Bill--

I slightly disagree with your interpretation of CFR regulation # 22.935, specifically what is a Cellular Telephone"
Cellular is defined in CFR 20.12 as "800 and 900 MHz bands".
http://edocket.access.gpo.gov/cfr_2006/octqtr/pdf/47cfr20.12.pdf
Cellular bands on Wikipedia are defined as 824-849, 869-894, 896-901, and 935-940 MHz.
Telephone is a device that converts electrical signals into sound, and converts sound into electrical signals. If you take the speakers out of a telephone, it is no longer a telephone.

:)

I also agree, coverage generally sucks unless you have a directional antenna, it's tuned at the band you're looking for, and you also are pointed straight down. We (Ivory team) had one phone go 1200 miles over 23 hours at ~20,000 feet, and not get a single message until it landed in a tree despite trying every hour. It had no directional antenna at all, just the built-in one. It also weighed like 90 grams, we decided to try to compromise on the "light" side.

Anyway... our lesson was, if you're going to use a phone or 3G data card, add a directional antenna. Helix and Yagi worked for us (though the Helix negatively impacted GPS altitude caltulations since it was pointed down and it was our only antenna.) Also, it makes more sense if you have a large pile of free phones and source code to compile the guts of the phones. Even so, we may spring for a satellite pager if we get serious about long-distance flights again.

See also paper: "GSM Applications for Airborne Platforms", who did some statistics on call success rates from a private plane. It wasn't great, as expected.
https://drachma.colorado.edu/dspace/bitstream/123456789/103/1/GSM+applications+for+airborne+platforms.pdf

Subject: [Balloon_Sked] Cellphones in balloons legal?

Hi Scott....Ron was using the EVDO card in his car to send the reports via a UI-View I-Gate in his car, not in the balloon.

Using the cellular phone network from a balloon is something that a few folks including the MIT students are promoting to the general public as a primary balloon position reporting method (even though it would appear to be prohibited even in balloons by regulation CFR# 22.935 - link shown below - Mike Manes of EOSS previously posted a similar link on this topic)....The method being promoted to the general public for balloons involves using cheap Boost Mobile cell phones with built-in GPS. They use websites such as Instamapper. com or

accutracker. com to see their reports....usually due to the nature of cell networks, once the balloon is high enough to hit multiple cell sites, no one wins and they get nothing back. I have a terrible time of it trying to use my cell phone even at my mountaintop house and I'm only 500 feet above average terrain....The MIT students got very lucky on their first flight and had a hit just before they landed and very spotty coverage during most of the flight on their first mission, but had nearly zero results on their next few missions. One of them did get his ham license and now uses amateur radio tracking with good results..... however, they still promote cell phones on their online Balloon Guide. Also, the Instamapper website (or perhaps the output of the Boost Mobile cell GPS) truncates the altitude above 22,000 feet so even though they might get some coverage higher than that, it just keeps reporting 22k feet. The only good use for cell phones on balloons would be as a backup recovery method as long it's in range of a cell tower once on the ground. So as a "Phone-Home" use after landing a cell phone system could be quite useful as a backup for APRS. However, it's much better to use a FindMeSpot unit for that as I've had great results using a Spot as backup recovery info once landed. I've already received a number of emails from folks who lost their cell phone balloon payloads and are asking about better ways to track them, so I try to steer them towards the amateur radio route.

The most successful use of cell phone reporting from a balloon was done by the innovative Ivory Copter folks (using a bunch of mylar party balloons) who pointed a directional antenna straight down from their payload, but even then they had spotty coverage. They were even sending down live still photos during the flight from the cell phone camera. Since they are on one of these lists, perhaps they can offer some insight into the legality of using cellphones from balloons.... it's possible that there is an exception to the rule for unmanned research balloons but I haven't found that info as yet.

I found this posting about cell phone usage in balloons and airplanes which seems to be quite clear about not using cell phones while airborne even in balloons:

>Cellular telephones installed in or carried aboard airplanes, balloons or any other type of aircraft must not be operated while such >aircraft are airborne (not touching the ground). When any aircraft leaves the ground, all cellular telephones on board that aircraft must >be turned off.

CFR regulation # 22.935
http://edocket. access.gpo. gov/cfr_2006/ octqtr/pdf/ 47cfr22.935. pdf

So in addition to the fact that government regulations appears to prohibit it, the very nature of cell tower sites means that it doesn't work well during flight.

Much better for license-free balloon flights to use Maxstream 900 MHz units (such as the 9Xtend) with the FindMeSpot as a backup.

However, the price will be substantially more than the $150 cost mentioned by the MIT balloon guide (our normal ARHAB flights will usually cost more than that just for the balloon and helium/hydrogen) . That is only achievable by using very small eBay surplus balloons, donated helium or hydrogen and then you'll still be nearly $200 for the Maxstream unit by itself....a safe estimate for a license-free payload using a Maxstream 9Xtend, GPS receiver and Spot payload cost would be about $400....not to mention the ground station costs of $200 for the ground unit, $50 to $100 for the antenna and the $149 a year subscription for the Spot unit.

So getting your amateur radio license would appear to be a fiscally responsible thing to do if you're planning to get into high altitude ballooning as you then can utilize the extensive APRS network and entice all those balloon-chaser hams who will happily climb remote mountains, hike into "Deliverance Country", scale trees, risk stampeding buffalos and tromp through alligator-infested swamps without hesistation in their quest to find your APRS balloon payloads.

6934. Project: Traveler Flight Status

Yahoo group: GPSL (2009 — 2010)
Date: 2010-05-01 02:28:34 UTC
From: Zack Clobes
Topic: 6934 Message: 6934

Other than winds-aloft, everything is looking good for tomorrow's flight.
We plan on filling at 7:30 at the Hutchinson Airport (Wells Aircraft), and
launch around 8:30.

The winds upstairs are pretty nasty - straight out of the south-west,
varying between about 40mph and 140mph. Our 2 hour flight will be landing
about 2.5 hours (by car) from us. If there's anyone down-wind in the
Manhattan area, we would be appreciative of any tracking assistance.

We will be chasing on UHF 446.000MHz. My cell number is 620-960-6898.

I have my website updated for tracking and (live) Twitter updates.

Direct Twitter updates at http://twitter.com/projecttraveler/

Tracking is coming from W0ZC-11 and AJ0NR-11.

Hi Paul,

Yeah, Kaymont does run out of inventory from time to time, and there's about a 90-day lead time on orders. So we generally keep at least a 3-month supply on in our own inventory. At least once, we've bought out all of Kaymont's stock with a single order with the balance on back order.

Scientific Sales distributes the other Japanese make latex balloons. We've had some bad luck with some of their products, including a 2000 gm that a 2" diameter hole in it, circled in magic marked and labeled "HOLE" that wasn't discovered until we rolled it out on launch morning. We asked for a refund, but all they offered us was a credit.

Well, I'm not ready to dis the Chinese product quality any more. All
the Li-ion's in EOSS payloads are Chinese, and so is the balance charger.
They've all performed darn well for us over the last 3 years and 30 flights.

I see that Ningbo Yunhaun does have an ISO 9000:2000 Cert, and that's
no mean feat, having struggled thru that process at the Ol' Ulcer Factory
years ago. I guess what they need is a US distributor.

Was that $80 price retail or OEM to distributor pricing?

Morning All.

Well NSS-48 was scrubbed due to weather. it's dry and nice nd clear, and ground winds like 5 MPh. but upper winds are like 200 Mile + flights and 90% chance of landing in lake Michigan. So tenetive re sked is next Sunday.

But i have a question. How does the whole prediction machine work?

I know it's based on the ball trak program. But what I'm trying to see how it works is where does it get it's sounding datas sets from?

I'm somewhat in a no mans land. as far as NWS balloon launch sites go. Im in EN43xo (roughly 43N and 90W) So pretty close to equidistant of three sounding sites

GRB, MPX, and DVN.

And when i run a prediction for each of them i get a different flight results. which of course is expected. Like just now i ran them. and the results came to be as follows the results is bearing in deg and distance in miles

GRB-43.7/207
MPX error
DVN 53/209

Ok now station list how does that work? Like the wisconsin list, http://nearspaceventures.com/w3Baltrak/htdocs/stationlist.html#WI there are 48 of them! I know balloons do not get launched from all of these, there s only one actual launch site GRB (Green Bay)
The closest to the actual launch site for today is called CMY, it's like 5 miles away.and it's report is

CMY-47.2/211
It's location is shown as
CMY MCCOY (USA-AF) 43.97 -90.73 256

Next closest of VOK
VOK VOLK/CAMP DOUGLAS 43.93 -90.27 277

It's about 23 Miles apart.
And it spits out this for a prediction,
VOK 47.2 /208

Close but again different.

So with only GRB as a balloon site in WI and the other two MPX and DVN being clsosest to me.

How is this actually working? When i choose station CMY say, is it looking at the three data sets and averaging them out by weight of how cloes to each one CMY is?

or what is actually happening when I choose CMY?

Joe,
The Air Resources Laboratory of NOAA uses the sounding data to make predictions at various air fields across the country. A simple view would be a weighted average of nearby soundings.
There are no sounding balloons in Indiana. I tend to use the ILX from Lincoln, Illinois since most of the upper air masses move from west to east. I will also use ILN in Wilmington, Ohio as a check, and more often for the winter flights. Generally, when flying from Greencastle, I use the IND (Indianapolis predictions), although I have used BMG (Bloomington, IN) and HUF (Terre Haute).
The set of predicted distance and headings are typical for the expected scatter from the models.
Personally, the bigger error arises from the fact that we use a predicted wind field for one moment in time and our flights last two hours (or more). I always run predictions using winds from T-3 hrs to T+3 hrs (and an even wider time spread if a frontal passage is nearby).

Joe...copy the whole GFS prediction file text, save it on your drive, remember what you named it and it will work on the PC version of Balloon Track.

MPX error
DVN 53/209

Ok now station list how does that work? Like the wisconsin list,
http://nearspaceventures.com/w3Baltrak/htdocs/stationlist.html#WI
there are 48 of them! I know balloons do not get launched from all of these, there s only one actual launch site GRB (Green Bay)
The closest to the actual launch site for today is called CMY, it's like 5 miles away.and it's report is

CMY-47.2/211
It's location is shown as

CMY
MCCOY (USA-AF)
43.97
-90.73
256

Next closest of VOK

VOK
VOLK/CAMP DOUGLAS
43.93
-90.27
277

It's about 23 Miles apart.
And it spits out this for a prediction,

VOK 47.2 /208

Close but again different.

So with only GRB as a balloon site in WI and the other two MPX and DVN being clsosest to me.

How is this actually working? When i choose station CMY say, is it looking at the three data sets and averaging them out by weight of how cloes to each one CMY is?

or what is actually happening when I choose CMY?

If you are using the Flight Track add-in for MapPoint, you can copy the GFS prediction text to the clipboard and paste it into the New Flight Prediction dialog. From there, it displays the prediction on MapPoint. More details here

http://www.surfingsatellites.org/flighttrackhelp/FTWorkFlow.htm#predict

6945. PT 2010a Flight Results

Yahoo group: GPSL (2009 — 2010)
Date: 2010-05-01 22:15:15 UTC
From: Zack Clobes
Topic: 6945 Message: 6945

We launched this morning a few minutes past 8:30 from the Hutch airport. Skies were partly cloudy with a rain-ish layer around 10,000'.

We overfilled the 1000g balloon (somewhat intentional considering the winds aloft), and wound up with an ascent rate around 1500'/min. The Canon camera running the CHDK firmware worked great, and we recovered over 300 photos during the flight. Unfortunately, we seem to have picked up a bit of moisture as we passed through the rain cloud, which quickly froze to the camera window. Most of the photos had a series of blurs all over the photo. :-(

The new controller design worked well until we hit 10,000 meters, when it quit reporting GPGGA strings. The GPS engine is an Inventek ISM300-F2, supposedly with the version 4 ballooning firmware. It is outputting at 4800 baud, and worked great again after passing back under 10km on the way back down. This was a major bummer that needs to be resolved right away...
Below are a couple of GGA samples - one good one, and one bad one.

Good
W0ZC-11>APRS:$GPGGA,135719.000,3820.0102,N,09733.9293,W,1,11,0.9,9824.1,M,-26.8,M,,0000*5D

Bad
W0ZC-11>APRS:$GPGGA,135931.006.8,M,,0000*63

Burst happened at 9:38 at 95,820'. Recovery was made by 11:49am after walking nearly a mile across 3 creeks and 3 fences. We had a good lunch at a pizzeria in Manhattan.

I will get some photos uploaded, hopefully yet this evening to www.projecttraveler.org/

Zack....I've flown the Inventek ISM 300-F2 GPS modules (with the balloon firmware) for dozens of flights now with excellent results...last time with a recent UAH flight we dropped at over 12,000 ft/min at burst (parachute problem)...and it still maintained a lock. Since I've added the active Sarantel helical antennas to my Inventek board, I now get over 8 to 11 satellites throughout the flight.

Even when the Inventek unit loses lock, you'll still see commas for the lat/lon/sats fields...and the satellite fields will be 0, not a complete absence of those fields as you show. I would check to see if there may be a parsing issue in your code when the altitude field increases by one digit as it gets above 10,000 meters. 10km is too low for there to be a DoD 60k kind of limit problem.

I've found, and I believe fixed the GPS > 10km problem. It was a combination of a buffer being one byte too small, as well as a variable that wasn't getting cleared out between reads of the GPS. Basically, because I couldn't get a good read on the GGA string that would fit into memory, the controller was concatenating two random pieces of strings together and calling that the GGA - that's why I was transmitting what appeared to be an abbreviated GGA string...

After looking back in the logs, it appears that one altitude did happen to make it through the parser by chance. I have a single position at 14:11:32 at an altitude of /A=052626.

While myself I of course welcome new groups to our adventures. But this type of HYPE has me really scared as to how many people will do this without learning any regulations, or any of the laws governing these flights. With the popularization of this activity in these ways how far down the road are we going to get bfore something bad happens because someone diddn't follow the laws. And in result we end up with ultra tight laws similar to the stuff high power rocketry has.

Maybe we can get Paul to voluntarily try to regulate who gets balloons? Kinda of like Ravens/Aerostar does? Make sure the balloons get to groups that have done flights before or have been mentored by other groups, and not to sell to balloon Boy's Dad in Colorao?

I know this sounds Bad. But with all the press lately that never ever mentions that there are laws that control these flights. it's just inviting anyone to do it without any knowledge at all of the laws.

6956. 70,000 foot Repeater - should be able to work from VE4-VE6 and northern US.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-05-06 00:45:45 UTC
From: lpcoates
Topic: 6956 Message: 6956

The first SABRE high altitude balloon launch of 2010 will take place on May 8 at 1400 UTC. We expect that the balloon will be aloft for approximately 2 to 3 hours. What is unique with this flight is that we will be flying a simplex repeater on 147.570. This is a store - forward simplex repeater. You use it by transmitting a short message on simplex at 147.570. When you unkey you should hear your own communication back. Anyone else within range of the repeater will also hear that transmission from the balloon. They can then respond the same way. Without flying duplexes etc we should be able to facilitate communication over a very long distance. We believe that in theory once the balloon gets above 30,000 feet (approximately 30-45 minutes from launch) stations from Manitoba, Saskatchewan, Alberta, Montana and North Dakota and possibly further will be able to hit the repeater and in theory communicate with each other. If you have a directional antenna, point it at Saskatoon or 52N, 106W.

To encourage use of the repeater, the Saskatoon Amateur Radio club is sponsoring an award for communications through the repeater.

The website for VE5AA has the details of the award under the Sabre 9 link.

We would appreciate it if you would publicize the repeater any way you can to try to encourage hams to try and make a contact.

The Saskatoon Web site is for this May 8 Saturday launch is
http://ve5aa.dyndns.org/Balloon/sabre_9.html

Documentation and images from their previous launches are here
http://ve5aa.dyndns.org/Balloon/index.html

Thanks

Bruce - VE5BNC

http://www.cnn.com/2010/TECH/05/06/crowdsource.gulf.oil/index.html?hpt=T1

(CNN) -- Here is what MIT student Jeffrey Warren plans to do Thursday:

Walk up and down the Louisiana coast holding a kite string that's tethered to a helium-filled trash bag and a point-and-shoot camera.

The set-up may sound goofy. But Warren's aim is serious.

Hi Mike, And all.

We somewhat talked about this once a while ago. And i wonder if now is the time that we all begin to form a organization for ARHAB activities.

Like the rocketry guys have Tripoli and NAR. Amateur Radio has the ARRL, (wether you like the ARRL or not they play a major role on what happens in the amateur radio hobby)

With the ever increasing publicity of launching things on balloons, and how they say it's soo cheap and how anyone can do it. I'm thinking it's maybe time to form an organization like all the above mentioned, as to a place people that are interested in doing these flights can go to to get more information on how to do it legally and safely etc..

Whats everyone think?

I would advocate a group origanization like NAR. I tried last year to look into group insurance without success. An organization like NAR has rules to follow that I imagine helped them get insurance.

I'm all for a national / international organization. A central place to learn about HABing would be good for the hobby, IMO.

And while insurance would be nice it does tend to be rather limited in scope. My homeowner's liability policy cover HAB activities. I have a $1 million dollar rider that covers all my hobbies as long as they are not for profit.

I am a former NAR member and current Tripoli Rocketry Assoc. member. Both groups have a $1 million liability policy that comes along with membership. The policy covers rocket flights that follow the safety code of each organization. I'd guess that a similar policy would be available for HABing but I'd guess members would need to have some rules to follow for the coverage. FAR 101 would probably be sufficient.

As I wrote the above I recalled that the rocket flights covered have a limited geographical area from the launch area. HABing distances are somewhat greater than hobby rocketry so that might be an issue.

I guess my feelings are a "Yes" to an organization for HABists and that an organization would probably be necessary for any liability policy to be established for the members. I'd have to believe that there is less liability in a HAB flight than a high powered rocket flight (and I know from experience that HPR is a safe endeavor despite its appearance).

Hi Joe,

IIRC, the subject of forming a national ARHAB organization was on the agenda at a GPSL conference a few years ago, but it got pushed off the the end of the schedule so we could get to more important stuff, like getting a weather brief, trajectory forecast and moving the launch site, or some such nonsense :=).

At the time, there seemed to be a general consensus that maybe the time was right, so maybe we could add it to this year's agenda - except sked it for the morning session this time.

Well back from the flight, and If we can find out what the make and model of GPS this was. it would be good to be able to add it to the list of ones to avoid.

Winds aloft were still a tad too brisk to use the 2000 gram balloon, so we flew a 600 gram size. launch was windy winds 10 to 15 gusting to 25, but it left with no problems. The GPS, Failed in it's altitude test. worked perfectly to the 60K mark, but once above it, it either did nothing or it spit out locations that were absolutely impossible. Like in the 60 seconds between transmissions, it would travel like 400 miles. At the measured rate of climb and the fine judging of the predicted landing spot we estimated a 95,000 burst level or so. it fits right in with the predicted profile within a mile. The payload landed safely in the back yard of a farmer. The chase teams were talking in the street thinking of how to go and check into the area it's believed to be in, and were about to go and ask the property owner if they can go in and look around, when the farmer came walking from around the back of the house with payload in hand. Saying,, "Are you guys looking for this"?

Now to find a better GPS.

I have a script somewhere that will take the GPRMC's and GPGGA's and split them out into a CSV file. Then I've used some spreadsheet formulas in OpenOffice.org to calc the ascent/descent rates, and even to plot them.

I haven't used it in a few years, but if you want, I can try to dig it out.

You are speaking of the COCOM limit. Try a Sparkfun Venus634FLPx or equivilent. You may exceed altitude or speed (check the specs) but not both on this unit and there are others you just have to look.

Hi Joe,

It depends really,
In my experience SIRF III module will go past the 60,000ft limit however then stop working at ~78k ft, they sometimes start working on the way down though have also required a reset before regaining lock.

Ublox modules do work above 60k ft and if set to Airborne mode are rated to work up to 50km (164k ft) - finally there are some ublox modules that are relatively cheap and easy to work with - check out the Falcom FSA03 and the breakout board from Esawdust.

The other GPS of choice is the stalwart Lassen IQ which goes past 60k and has always worked however high it has gone.

The Venus chipset is another choice - the initial batch apparently didn't work above 60k but the manufactures then corrected this and claim that they do work - not sure if anyone has tested this. Unfortunately what is said in the specs doesn't often correspond to the modules regarding COCOM so needs to be tested.

James

Hi James,
And everyone on the list.

Very good information below people! Thanks and keep it coming. We will need one that is absolute sure to work way up there, I mean WAY UP THERE! Like way above 125,000.

Yeah we tested an un tested one yesterday. And while below 60K it worked perfectly. FAST lock on. the beacon was set to transmit every 60 seconds. and every time I powered up the unit, it must have locked on in less than 60 seconds because every time the first transmission would indicate right where it was no matter where it was.

But once it went above 60K, we had the micro trac send even invalids so it would either repeat the last position with slight number differences, like a few feet higher or lower, or slightly different lat long to it would move like a quarter mile or so. But then some reports would suddenly make it jump several hundred miles.out into lake michigan or even central michigan state.

But after burst and it got below 60K it resumed to report perfect positions exactly where it should have been according to the predictions.

And it finally landed and was retrieved. If i adjusted the estimated burst altitude from 93K to 98K it lands within like 1000 feet of the prediction! Not Bad!

So Anyway, we are in the need of a GPS that is guaranteed to work way up there well past even 125,000, so looking for recommendations.

Thanks All!

Hi Joe,

I think you'll find that few have direct experience with how well GPS units function at that altitude. As far as I know, there aren't any that have known limitations at 125,000 ft that aren't already present at lower altitudes above 60,000 ft. The only possibility I can think of is software limitations that might prevent calculation or reporting of altitudes above 32,767 meters (that's the maximum value of a 16-bit signed integer).

Ok, now I'm confused where does this 16 bit thing come into play and why?

Reason saying is we have had the Garmen hocky puck exceed that altitude
32,767 meters (107503 feet) several times, well in to the teens Like
112,000 and 118,000 feet. This is frustrating he he he,,

It may not come into play at all on a particular model, but if the altitude is stored or converted to a 16-bit integer at some point, it'll only work up to 32,767 meters. You'd have to know the GPS's internal microcode to determine that (not likely to see).

So even if a manufacturer says it'll work above 60,000 ft, it may not work at *all* altitudes above 60kft.

Data on real-world GPS experience above 120 kft is sparse to say the least. No one goes there..... :)

SigHi Joe

The fellow Garmin who did the presentation for us at GPSL 2009 mentioned that their code has an arbitrary limit built in based on the routines they use to calculate their positions. In consumer grade units, to make calculations faster to perform they use approximations based on a GPS being used near the ground so they become inaccurate at very high altitudes. If I recall correctly their formulas start to become inaccurate when you're 2 or 3 thousand feet up so their consumer code is designed to stop working before that happens. I suspect other manufacturers do similar things.

I love all these gadgets we get to play with now that we diddn't have 20+ years ago. While this program of Bills and Hank's revisions is almost as old as ballooning itself,, I have never used it till i tried it last night.

seems pretty cool except for one thing,, that I wonder about

What are the Min diameter and max diameter windows.

Ok onto another when i plug in the spec's for yesterdays flight, it jives right on with everything that happened.

isn't it cool when things match the real world?

BUT

when i plug in what we would have flown if the winds were Ok would have been a 2000 gram balloon using H2 for gas, a 1.25 pound payload, and a extra pound of free lift, (2.25 pounds lift on the balloon neck with no payload)

Punch in those numbers and the program wont show me reasonable lift amounts,

what do i need to do to be able to see say 1 pound of free lift?

I tried re sizing the window like any regular "Windows" you do and a grab and drag doesn't work.

Joe

SigUncheck "default values" then reduce the "Min Dia" to something smaller then click "calc". Play with that and you will get what you're looking for.

Why would it become in accurate at all. Does this mean the ones that EOSS uses before they even get off the ground are no good sitting on the bench? i mean they are higher than that right/

Hi Rodney

I've flown this to 105 and 109 thousand feet and it worked great on ascent. On the 105.000 foot flight it lost lock at burst and never regained it. I was told that there is a configuration item to prevent this which is stored in the batter backup up ram. Bill Brown also flies them regularly.

SigHi Joe

The formulas and therefore the computing power required to determine an exact fix everywhere between the ground and earth orbit are much more complex so would require much more computing power than consumer GPSs have. This is why consumer GPSs cost less than a good steak dinner and runs all day a battery while industrial/military grade units cost as much as a car (or house) and need a batteries a lot bigger than a 9v. Everything's a compromise. Your car's speedometer was never designed to work at 700 mph but it works just great at normal car speeds where it was designed to work. Your rolling ball clock works great for regular time keeping but one that resolved down to the microsecond would be a completely different machine. The GPS units that EOSS and other balloonist use were designed to work from lower than ground level (if you could find a deep hole where you could receive satellites) to tens or hundreds of thousands of feet up so they're as accurate as any of us need within those ranges.

I use the Tiny Trak packets and dump the whole thing into a spreadsheet. If
you go to my webpage, nearsys.com, check under past flight records and
you'll find several flight reports with APRS spreadsheets you can look at.

Also, one of my past articles for the Citizen Scientist gives an
explanation.

Balloon Track for Windows can do this.

http://www.eoss.org/wbaltrak/

It is actually a side benefit to the original purpose of this function. When Balloon Track is used to monitor a flight in progress it creates a spread sheet with lots of info for easy post-flight analysis. However, there is a "Simulation" option in Balloon Track that allows you to read an APRS capture file into the program and process it as if it is a live flight. Thus, in the process, BT creates the spreadsheet which contains many derived parameters, Ascent rate among them. Here is the skinny since it isn't too well documented on the web page.

The function is a bit buried but .

On the setup screens

1.) On the "Flight Info" tab, enter the callsign you want to get the data for. (required)

2.) Disable Live Data Capture (not really necessary since the program will only observe the callsign indicated on step one)

a. On the Packet Parameters tab click on "Setup Comm port or TCP/IP"

b. In the Commsetup screen select "Comm Port" and then in the Comm Port Settings box set Comm Port to "No Comm"

3.) Close the Setup screens

4.) On the main menu select "Packet Data/Packet Terminal"

5.) When the Packet screen opens Select "File/Open Simulation" and specify your log file.

When you click "Open" in the file selection box, that file is loaded into Balloon Track and the program immediately starts processing the file line by line. There is a simulation "speed control" you can use to speed up this function a bit. I originally wrote this capability into the program so I could watch it work on data in simulation mode and watch the code execute. This made designing some of the functions much easier to troubleshoot. Once I was finished with the coding process I removed the menu entry for it. But after the very first flight with the simulation mode removed, I quickly realized the utility it represented and re-activated its menu selection item.

Balloon Track will read many different formats of data. If the data includes Altitude information and GPS timestamps it will calculate Ascent and Descent rates. It places this along with lots of other captured and calculated data into a spreadsheet file (CSV) that is assigned the name "Flight_Data_YYYY_MM_DD.csv" where Y, M and D represent the date when you ran the simulation.

I run the KPC3 Log from our airborne APRS systems through this routine after each EOSS flight and build the data files from liftoff to landing and then use that data to generate the recap information. You can see the CSV spread sheet files generated by this process in almost all recap pages of recent vintage, for instance:

http://www.eoss.org/ansrecap/ar_160/recap150.htm

At the bottom of our last recap in the data section is an entry for:

eoss-150_ae0ss-11_Flight_Data.csv - airborne only KPC3 Log ripped to spreadsheet format

Download this file which was generated in simulation mode by BT and you can see the layout of this spreadsheet. One note. There is an entry for "System Time" (2nd column). In real-time operations this is handy if the APRS system is not pumping out timestamps as it can be used for intra packet calculations of distance and speed. However, when processing the file in simulation mode, it means nothing, you need that "GPS Time" field to do any post flight analysis.

Here are the fields in the spread sheet

"Callsign"

"System Time"

"GPS Time"

"Altitude(ft)"

"Ascent Rate(fpm)" Calculated between sequential packets

"Grid X(mi)" EOSS uses a Grid for recovery, you can disregard this

"Grid Y(mi)" EOSS uses a Grid for recovery, you can disregard this

"Latitude"

"Longitude"

"Track" Calculated between sequential packets

"Speed(mph)" Calculated between sequential packets

"GPS Track" Read from APRS file directly NOT CALCULATED

"GPS Speed(mph)" Read from APRS file directly NOT CALCULATED

"Bear From Launch" Calculated for each packet packet

"Dist From Launch(mi)" Calculated for each packet packet

"Dist. to LOS(mi)" Calculated for each packet packet

Units of measurement change to meters and kilometers if the program is set to run in that mode.

Hope that is useful.

As long as I'm not inundated, I'd be glad to run aprs logs through the program for folks who do not have it installed.

That spreadsheet was perfect dude!

Now how did you take the raw data from like what was recorded on finu or aprs.fi and get it in there/
